HEALTH STATISTICS

FROM THE U.S. NATIONAL HEALTH SURVEY

Volume of X-ray Visits

United States

July 1960 June 1961

Statistics on volume of medical and dental X-ray visits, by area of body x-rayed, place of X-ray, type of X-ray, age, sex, race, residence, geographic region, family income, and education. Based on data collected in household interviews during the period July 1960-June 1961.

Robert T. Little, Chief, Automatic Data Processing

The U. S. National Health Survey is a continuing program under which the Public Health Service makes studies to determine the extent of illness and disability in the population of the United States and to gather related information. It is authorized by Public Law 652, 84th Congress.

CO-OPERATION OF THE BUREAU OF THE CENSUS

Under the legislation establishing the National Health Survey, the Public Health Service is authorized to use, insofar as possible, the services or facilities of other Federal, State, or private agencies.

In accordance with specifications established by the National Health Survey, the Bureau of the Census, under a contractual arrangement, participates in most aspects of survey planning, selects the sample, collects the data, and carries out certain parts of the statistical processing.

VOLUME OF X-RAY VISITS

SELECTED FINDINGS

During the 12-month period starting in July 1960 the U. S. National Health Survey, in its Health Interview Survey program, collected information about medical and dental X-ray visits. Since about half of the total radiation dosage to the whole body of an average person is accounted for by medical and dental X-ray exposures, it is of interest to study how these X-rays are distributed in the several age and sex groups in the population of the United States.

During a 12-month period members of the civilian, noninstitutional population reported that they had made an estimated 85 million visits to medical facilities for medical X-rays, and about 49 million visits for dental X-rays. During a medical X-ray visit one or more areas of the body were x-rayed; a total of about 93 million areas of the body were x-rayed during the 85 million visits. An X-ray of an area of the body may have included one or more film exposures, one or more fluoroscopic views, or one or more X-ray treatments. No attempt was made to collect information about the number of film exposures, fluoroscopic views, or ports used for treatment; in addition no data were collected about treatment with radioactive materials, including radium and radioisotopes.

The chest was the area of the body x-rayed most frequently, with an estimated 51 million visits. Next in terms of frequency were X-rays of the extremities, about 14 million visits. Most of the 85 million medical X-ray visits made by individuals were for diagnostic purposes; there were 82 million diagnostic X-ray visits compared with about 3 million visits reported for treatment; about 2 million of the visits were made for both diagnosis and treatment.

This report was prepared by Charles S. Wilder of the U. S. National Health Survey staff.

Males had a higher rate of medical X-ray visits than did females, but the reverse was true for dental X-ray use. Nonwhite persons between the ages of 15-44 had more medical X-ray visits per 100 persons than did white persons. The greater rate of X-rays of the chest by nonwhite persons accounted for this racial difference. On the other hand, rates of visits for dental X-rays were higher for white persons than for nonwhite persons.

As family income and educational attainment of the head of the family rose, the rate of dental X-ray visits also increased. For medical X-ray visits, an increase in the X-ray visit rate was correlated with rise in educational level of the head of the family, but the rate remained approximately the same for each income group.

Residents of the Western States had the highest rate of medical and dental X-ray visits. Persons residing in urbanized areas of the country, using areas defined in the 1950 Census, made greater use of medical and dental X-ray facilities in proportion to population than did residents in the rural areas.

A higher percentage (50.0) of medical X-rays of various areas of the body were performed in the hospital than in other places. The percentage in hospitals includes both outpatients and inpatients. About two out of each five chest X-rays were made in a place other than a hospital or doctor's office, including such places as health departments, mobile X-ray units, industrial places, or schools.

SOURCE AND LIMITATIONS OF THE DATA

The information presented in this report was obtained from a continuing household interview survey of a probability sample representative of the civilian, noninstitutional population residing in the United States. During the 12-month period,

July 1960-June 1961, interviews were obtained in approximately 38,000 households containing about 125,000 persons living at the time of the interview. Data about health, social, and demographic characteristics of each household member were recorded on the questionnaire reproduced in Appendix III. Information on the volume of X-ray visits and areas of the body x-rayed was obtained in response to questions 21-25.

A brief description of the statistical design of the survey, the methods of estimation, and general qualifications of the data obtained from surveys is presented in Appendix I. Since estimates shown in this report are based on a sample of the population rather than on the entire population, they are subject to sampling error. Therefore, particular attention should be directed toward the section, "Reliability of Estimates," which contains charts indicating relative sampling errors and instructions for their use. The sampling errors for most of the estimates are of relatively low magnitude. However, when a number, or the numerator or denominator of a rate orpercentage, is small, the sampling error may be high. In these instances, the estimates must be interpreted with caution.

Definitions of certain terms, and particularly those related to X-ray visits, are explained in Appendix II. Some of the terms have specialized meanings for the purpose of the survey. Familiarity with these definitions will assist the reader in interpreting the data. For example, an X-ray visit was included if X-rays had been used for film exposure, fluoroscopy, or treatment. If radioactive materials, such as radium or radioactive isotopes, were used for treatment or diagnosis an X-ray visit was not counted.

A general limitation to all data obtained by household interview is that the data are no better than the respondent's knowledge of and willingness to discuss his affairs. To determine the format which would elicit the most accurate and complete information, pretests of the X-ray questions were conducted, and the answers were compared with X-ray records of sample populations (see Appendix IV). These pretests indicated that memory recall of X-ray visits was satisfactory up to a period of three months. Beyond that period, however, a larger proportion of X-ray visits were not reported in the interview. Therefore, the X-ray questions were phrased in terms of a three-month reference period. As indicated in Appendix IV, visits for treatment were less well reported than visits for diagnosis.

Questions were formulated to elicit information in terms of the X-ray visit rather than the

X-ray exposure since it was assumed that respondents would be likely to know how many times a visit was made during which an area of the body was x-rayed or fluoroscoped, but that they would not know the number of exposures (films or fluoroscopic views). For similar reasons the X-ray visits were classified in terms of six general areas of the body rather than such specific parts of the body as individual bones or internal organs. The use of radioisotopes as a source of radiation for medical purposes was not included in these data because relatively few respondents would know sufficient details about this application.

MEDICAL X-RAY VISITS

Volume of Visits

From data collected during July 1960-June 1961 it is estimated that about 85 million visits were made to medical facilities for medical X-rays during this period (table 1). One visit was counted each time a person went to a doctor's office, hospital, or other facility to have one or more areas of the body x-rayed. Since the same person may have had more than one such visit during the period, this does not mean that 85 million persons had medical X-rays during a year's time.

Respondents in the household health interview were asked how many times each household member visited an X-ray facility for a medical or dental X-ray during the three months prior to the week of interview. No data about X-ray visits were collected for active military personnel, institutionalized members of the population, or deceased members of the household.

During an average three-month period about three fourths of all persons, who had X-ray experience made a single visit for a medical X-ray (table A). The remainder made two or more visits. As age increased the frequency of multiple visits rose; about one third of the x-rayed persons aged 65 years and over made two or more visits to an X-ray facility during a three-month period. Multiple visits were made chiefly for treatment X-rays, while the majority of single visits were for diagnostic purposes.

On the average there were about 48 visits a year for medical X-rays for each 100 persons in the population. Relatively few persons under 15 years of age had an X-ray visit, but from 15-64 years of age the rate remained quite stable except as noted below. In general, persons between the ages of 45-64 years reported the highest rate of medical X-ray use.

The rate of medical X-ray visits was about the same for members of white and nonwhite races for all ages combined and for some of the age groups (table 1). There was a substantial racial difference in the rate for the age groups 15-44 years for both sexes combined and for females; moreover, there is an apparent, but not significant, difference in the rate for males aged 15-44 (table 1 and fig. 1). This difference is partially

explained by the higher rate of chest X-ray visits among nonwhite persons in the middle years of life (table B). No such racial difference in rates was present in the data for other areas of the body x-rayed.

The rate of X-ray visits for males was higher than that for females in each age group (table 1 and fig. 2). The sex difference in rates was marked among persons 45 years and over, probably because of the high frequency of chest X-rays among males. The contradictory data in table 1 showing higher rates for nonwhite females than for nonwhite males in the age groups 15-64 may

¹The rates shown in figures 1-6, 9-15 are plotted on semilogarithmic scale so that visual comparisons can be made of relative amounts of variation within and between individual curves.

be due to sampling error since the difference in rates is not statistically significant.

There were also differences in the rates of medical X-ray visits by place of residence (table 2 and fig. 3). Residents of urbanized areas reported the highest rate, while rural-farm residents had the lowest rate. This urban-rural difference, which has also been noted in statistics dealing with the use of other health facilities, e.g., physician and dental visits, may be due to the lesser availability of X-ray facilities in rural areas. The sex difference mentioned above ap-

pears to be less pronounced in rural areas than in urban areas, but this may be an artifact resulting from sampling error. The age curve of the rates was substantially of the same pattern in each area of residence.

Residents of the Western States reported higher rates of medical X-ray visits than did residents in the Northeast, North Central, and South regions (table 3 and fig. 4). The lowest rates were reported from the Northeast. The sex difference in rates was most pronounced in the North Central region, and least in the South. The

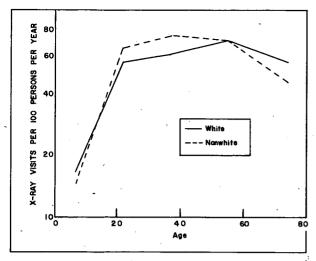

Figure 1. Medical X-ray visits per 100 persons per year, by race and age.

age changes in the rates were about the same in all four regions, except that in the West the rate for persons 15-29 years of age was somewhat higher than the comparable rate in the other regions. Males in this age group had a much higher rate than did females. A possible explanation is

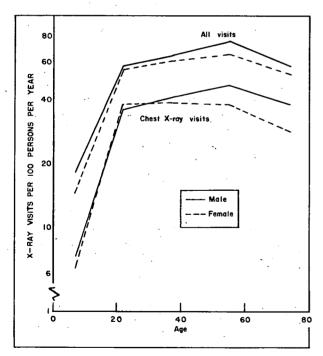

Figure 2. Medical X-ray visits and chest X-ray visits per 100 persons per year, by sex and age.

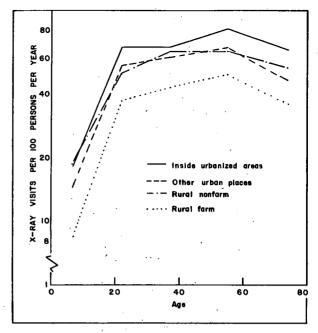

Figure 3. Medical X-ray visits per 100 persons per year, by residence and age.

that males in this age-sex group are known to have a high rate of injury and the injury rate is higher in the West than in any other geographic region (see Health Statistics, Series B, No. 37).

In general, the rate of medical X-ray visits was substantially the same in each age-sex-in-

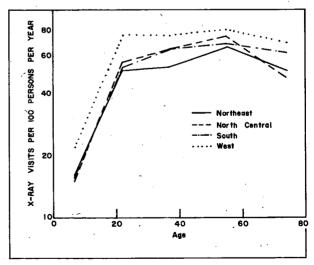

Figure 4. Medical X-ray visits per 100 persons per year, by region and age.

come group, except in three instances (table 4 and fig. 5). These three instances were: in the \$7,000 and over family income group, the higher rate of X-ray visits among males was more pronounced than in the other income groups; and for both sexes combined in the top income group the rate for the 45-64 year age group was higher than that for the same ages in the other income groups; and in the under \$2,000 income group the rate for females of ages 15-29 years was substantially higher than that in the other income groups.

There are several possible explanations for these differences. There may be less concern over the possible hazards of radiation for routine detection purposes in men than in women of younger adult ages. It is also possible that men more often receive X-rays in connection with their employment. Among higher income males in the 45-64 year age range, the high rate of X-ray visits could reflect a greater use of X-rays in physical examinations aimed at detection of lung cancer, cardiac abnormalities, and other conditions to which this group is considered subject to risk. In the upper income group a relatively high proportion of the X-ray visits were in doctors' offices.

Persons in lower income families have a high proportion of X-ray visits in hospitals. There may be an association between this and the high rate of X-rays, especially chest X-rays, in lower income women of childbearing ages. Women in this group, requiring the services of a physician for prenatal or postnatal care, or of a hospital for delivery, may frequently receive chest X-rays as a

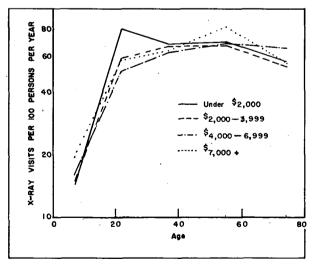

Figure 5. Medical X-ray visits per 100 persons per year, by family income ond age.

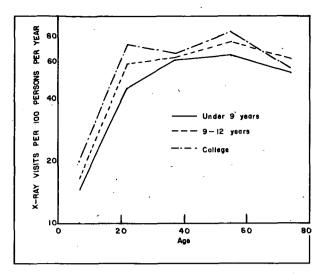

Figure 6. Medical X-ray visits per 100 persons per year, by education of head of the family and age.

part of physicians' assessments of their health. This is often done in prenatal clinics or at photo-fluorographic units in certain hospitals.

The rate of medical X-ray visits rose markedly with increasing levels of education of the head of the family (table 5 and fig. 6). Again within the two age groups, 15-29 and 45-64 years, the greatest variation among educational groups was noted. Table 6 shows the effects on the rates of medical X-ray visits resulting from cross-classification of family income and education of head of the family. The table indicates that the use of medical X-rays is related to educational level and that income does not influence this relationship to any great extent.

X-rays of the chest area were responsible for more than half of the medical X-ray visits (table 7 and fig. 7). A total of about 93 million gross areas of the body were x-rayed during the 85 million visits, or an average of 1.1 body areas per visit. Therefore during relatively few visits were multiple areas of the body x-rayed. The second area of the body in order of frequency of area x-rayed was the extremities. The sex difference in rate of X-ray visits noted for all visits was present in some of the data by area of the body, notably in X-rays of the chest and extremities, the two largest groups. However, females had the higher rate of X-ray visits for the lower

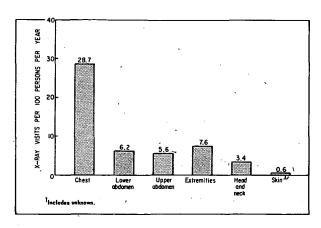

Figure 7. Medical X-ray visits per 100 persons per year, by area of body x-rayed.

and upper abdomen. X-rays of the head and neck were equal in rate between the sexes. It is probable that the peaking in the rate of X-ray visits for extremities for males aged 15-29 was caused by a high injury rate for this age group (see Health Statistics, Series B, No. 37).

There were about 82 million X-ray visits for diagnosis and 3 million visits for treatment (table C). About 2 million of the total of 85 million visits were for both diagnosis and treatment during the same visit: one area of the body was treated by X-rays while another area was x-rayed for diagnostic purposes.

About 89 million of the 93 million areas of the body x-rayed, or 96 percent of the total, were x-rayed for diagnostic purposes. The remainder were treated by X-radiation (compare tables C and 7). The chest and extremities were the most frequent sites of diagnostic X-rays with about 72 percent of the total number of diagnostic

¹The sum of visits by area of body x-rayed may be greater than the total number of visits, since during one visit more than one area of body may be x-rayed.

Includes unknown areas of the body

X-rays. Of the approximately 4 million areas of the body treated by X-rays, the skin and head and neck accounted for about 49 percent of the total.

There was a racial difference in the use of diagnostic X-rays. The rate of diagnostic chest X-rays was somewhat greater for nonwhite persons than for white persons. However, the rates for the abdomen and extremities were higher for white persons than for nonwhite persons. No racial differences were apparent for treatment X-rays.

Areas of the Body X-rayed by Place of X-ray

The place of medical X-ray differs substantially according to the area of the body x-rayed. Therefore, the place of X-ray was tabulated for each area of the body rather than for the X-ray visit. Three locations are shown in tables 8-10; hospital includes both inpatient and outpatient X-ray services, doctor's office includes radiologists and other doctors with X-ray equipment in their offices, and other includes such places as schools, mobile units, health departments, etc. The number of unknown places of X-ray included in this latter group cannot be determined.

The majority of X-rays for areas of the body other than the chest were performed in hospitals (table 8 and fig. 8). For the chest, about two fifths of the X-rays were made in other and unknown places. It is probable that most of these were diagnostic chest X-rays conducted for screening purposes by various agencies, such as health departments, industries, schools, and nonprofit health agencies. The largest percentages of X-rays performed in doctors' offices were for the extremities, head and neck, skin, and other and unknown areas of the body.

Table 9 shows the distribution by place for X-rays of the chest, and table 10 shows place of X-ray for other combined body areas according to various demographic, social, and economic characteristics. In general, smaller proportions of X-rays of the chest were performed in hospitals than corresponding percentages of X-rays of other areas of the body. Table 9 shows that in only three demographic groups were more than half of the chest X-ray visits reported as having been made to the hospital, namely, persons under 15, persons with family income under \$2,000 and persons residing in the New England States. Relatively small proportions of chest X-ray visits were made to the doctor's office, while larger percentages were made to other and unknown

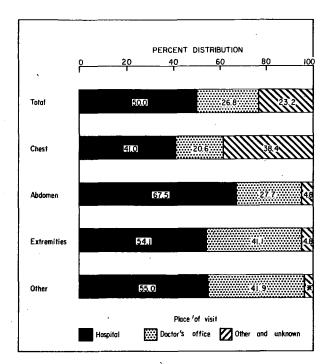

Figure 8. Percent distribution of areas of the body x-rayed by place of X-ray.

places of X-rays. For areas of the body other than the chest the hospital was the most frequent place of X-rays in all demographic classes.

The place of X-ray treatment, shown in table D, probably reflects the location of available equipment required for treatment of various areas of the body. Low-voltage X-ray equipment used for treatment of skin conditions is usually available in the dermatologist's office, Deep X-ray treatment for pathology of the chest and abdomen is usually performed in the hospital. The large percentage of treatment X-rays of the extremities occurring in the doctor's office perhaps results from the use of X-rays to determine proper reduction and placement of casts in fractures or dislocations. The percentages shown in this table are based on relatively small numbers and should be interpreted with caution due to high sampling errors.

DENTAL X-RAY VISITS

The data on dental X-ray visits will be more meaningful to readers if reference is made to other reports from the U. S. National Health Survey on dental care. Health Statistics, Series B,

Table D. Percent distribution of areas of the body treated by X-rays, by place of X-ray: United States, July 1960-June 1961

Nos. 14 and 15, covering the period from July 1957-June 1959, show data on interval and frequency of visits, and volume of visits, by the same variables shown in this report.

An estimated 49 million dental X-ray visits, or an average of 27 per 100 persons, occurred during the 12-month period from July 1960-June 1961 (table 11). Figure 9 shows a comparison between the age distribution of dental X-ray visits with the age distribution of all dental visits shown in Series B, No. 15, based on data collected during July 1957-June 1959. The two curves are quite similar, and give the impression that during one of each five dental visits a dental X-ray procedure is performed. In each instance the age group 15-29 years reported the highest rate of dental services.

There was a substantial racial difference in the rates of dental X-ray visits; the rate per 100 white persons was about twice that for nonwhite persons (table 11 and fig. 10). Such a difference in rates could imply lesser need for dental X-rays or inability or unwillingness to obtain them. Table E shows that within each racial group, the rate of dental X-ray visits rose remarkably with increased income. Since about 31 percent of the white population has a family income of \$4,000 or less as compared with 72 percent of the nonwhite population (table 21), it is probable that much of the difference between racial groups in the rate of dental X-rays results from factors associated with income.

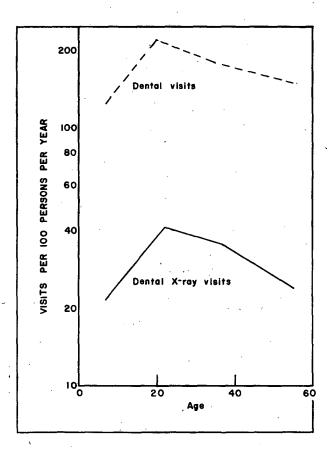

Figure 9. Comparison between rates per 100 persons per year of dental X-ray visits and dental visits (adapted from table 2, Health Statistics Series B-15, July 1957-June 1959), by ages under 65.

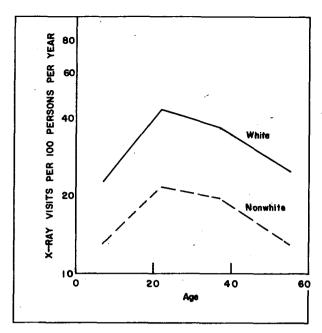

Figure 10. Dental X-ray visits per 100 persons per year, by race and ages under 65.

A considerable difference in rates by sex is present in the data shown in figure 11, with the rate for females higher in each age group than the corresponding rate for males. This sex difference was not noted for nonwhite persons. The

difference was marked in the age group 15-29 years, and may be explained by the use of dental X-rays for straightening of teeth and other dental care for cosmetic reasons. Another cause may be childbirth and associated increase in dental caries.

The rate of dental X-ray visits was highest in urbanized areas and lowest in rural areas (table 12 and fig. 12). The sex-age difference at ages 15-29 years was marked in urbanized areas of residence but the difference was smaller in other places of residence.

Persons in the West and Northeast regions of the United States had considerably higher rates of dental X-ray visits than did persons residing in the South and North Central States (table 13 and fig. 13). Except in the South the rate was highest for the age group 15-29 years.

The dental X-ray visit rate was directly related to the rise in family income (table 14 and fig. 14). There was a substantial increase in the rate for the income group \$7,000 and over compared with that for the next lower income group. Members of the highest income group probably make more use of orthodontia and of preventive dental practice through increased frequency of dental examinations than do members of the other groups. The persons in the lower income groups probably incur dental expense for X-ray visits as the need arises. This is suggested by the fact that for the age group 15-29, the rates are quite closely comparable for each of the three lower income groups.

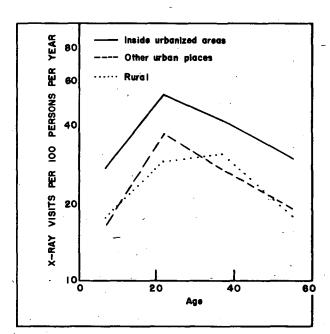

Figure 12. Dental X-ray visits per 100 persons per year, by residence and ages under 65.

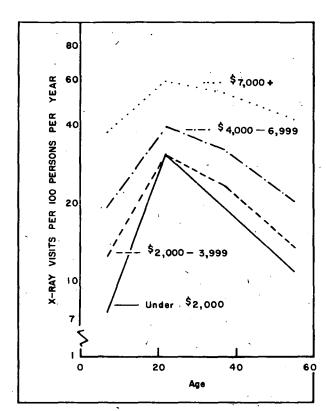

Figure 14. Dental X-ray visits per 100 persons per year, by family income and ages under 65.

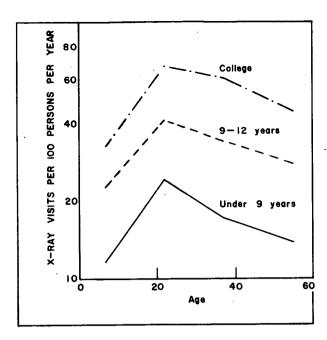

Figure 15. Dental X-ray visits per 100 persons per year, by education of head of the family and ages under 65.

Table 15 and figure 15 show a substantial rise in the rate of dental X-ray visits with increase in education of head of the family. The rise in rate closely resembles that shown in the previous table for family income. Such a similarity in rates is expected since, in general, higher income is associated with higher educational level (table 20).

Tables 16-21 show the populations used in computing the rates presented in this report.

DETAILED TABLES-

			rage
		MEDICAL X-RAY VISITS BY RACE, RESIDENCE, REGION, FAMILY INCOME, EDUCATION OF FAMILY HEAD, SEX, AND AGE	
Table	1.	Number of medical X-ray visits and number of medical X-ray visits per 100 persons per year, by race, sex, and age: United States, July 1960-June 1961	15
	2.	Number of medical X-ray visits and number of medical X-ray visits per 100 persons per year, by residence, sex, and age: United States, July 1960-June 1961-	16
	3.	Number of medical X-ray visits and number of medical X-ray visits per 100 persons per year, by region, sex, and age: United States, July 1960-June 1961	17
	4.	Number of medical X-ray visits and number of medical X-ray visits per 100 persons per year, by family income, sex, and age: United States, July 1960-June 1961	18
	5.	Number of medical X-ray visits and number of medical X-ray visits per 100 persons per year, by education of family head, sex, and age: United States, July 1960-June 1961	19
	6.	Number of medical X-ray visits and number of medical X-ray visits per 100 persons per year, by family income, education of family head, sex, and age: United States, July 1960-June 1961	a 20°
		MEDICAL X-RAY VISITS BY AREA OF BODY X-RAYED	
	7.	Number of medical X-ray visits and number of medical X-ray visits per 100 persons per year, by area of body x-rayed, sex, and age: United States, July 1960-June 1961	' 21
		AREAS OF BODY X-RAYED BY PLACE OF X-RAY	
,	8.	Number and percent distribution of areas of body x-rayed, by place of X-ray, according to age: United States, July 1960-June 1961	22
	9.	Number and percent distribution of chest X-ray visits, by place of X-ray, according to selected characteristics: United States, July 1960-June 1961	23
. *	10.	Number and percent distribution of areas of body (except chest) x-rayed, by place of X-ray, according to selected characteristics: United States, July 1960-June 1961	24
		DENTAL X-RAY VISITS BY RACE, RESIDENCE, REGION, FAMILY INCOME, EDUCATION OF FAMILY HEAD, SEX, AND AGE	
	11.	Number of dental X-ray visits and number of dental X-ray visits per 100 persons per year, by race, sex, and age: United States, July 1960-June 1961	25
	12.	Number of dental X-ray visits and number of dental X-ray visits per 100 persons per year, by residence, sex, and age: United States, July 1960-June 1961-	26
	13.	Number of dental X-ray visits and number of dental X-ray visits per 100 persons per year, by region, sex, and age: United States, July 1960-June 1961	27
	14.	Number of dental X-ray visits and number of dental X-ray visits per 100 persons per year, by family income, sex, and age: United States, July 1960-June 1961	28
	15.	Number of dental X-ray visits and number of dental X-ray visits per 100 persons per year, by education of family head, sex, and age: United States, July 1960-June 1961	29

¹ The sum of visits by area of body x-rayed may be greater than the total number of visits, since during one visit more than one area of body may be x-rayed.

 $^{^2}$ Skin includes an estimated 39,000 unknown areas x-rayed.

Table 8. Number and percent distribution of areas of body x-rayed, by place of X-ray, according to age: United States, July 1960-June 1961

APPENDIX I

TECHNICAL NOTES ON METHODS

Background of This Report

This report on Volume of X-ray Visits is one of a series of statistical reports prepared by the National Health Survey. It is based on information collected in a continuing nationwide sample of households in the Health Interview Survey, a major aspect of the program.

The Health Interview Survey utilizes a questionnaire which, in addition to personal and demographic characteristics, obtains information on illnesses, injuries, chronic conditions and impairments, and other health topics. As data relating to each of these various broad topics are tabulated and analyzed, separate reports are issued which cover one or more of the specific topics. The present report is based on the consolidated sample for 52 weeks of interviewing during the period July 1960-June 1961.

The population covered by the sample for the Health Interview Survey is the civilian, noninstitutional population of the United States living at the time of the interview. The sample does not include members of the Armed Forces, U. S. nationals living in foreign countries, or crews of vessels.

Statistical Design of the Health Interview Survey

General plan.—The sampling plan of the survey follows a multistage probability design which permits a continuous sampling of the civilian, noninstitutional population of the United States. The first stage of this design consists of drawing a sample of 500 from the 1,900 geographically defined Primary Sampling Units (PSU's) into which the United States has been divided. A PSU is a county, a group of contiguous counties, or a Standard Metropolitan Statistical Area.

With no loss in general understanding, the remaining stages can be telescoped and treated in this discussion as an ultimate stage. Within PSU's then, ultimate stage units called segments are defined, also geographically, in such a manner that each segment contains an expected six households in the sample. Each week a random sample of about 120 segments is drawn. In the approximately 700 households in those segments, household members are interviewed concerning factors related to health.

Since the household members interviewed each week are a representative sample of the population, samples for successive weeks can be combined into larger samples. Thus, the design permits both continuous measurement of characteristics of high incidence or prevalence in the population, and through the larger consolidated samples, more detailed analysis of less common characteristics and smaller categories. The continuous collection has administrative and operational

advantages as well as technical assets, since it permits field work to be handled with an experienced, stable staff.

Sample size and geographic detail.—Over the 12-month period ending June 1961, the sample included approximately 125,000 persons from 38,000 households in 6,400 segments. The over-all sample was designed in such a fashion that tabulations can be provided for each of the major geographic regions and for urban and rural sectors of the United States.

Collection of data.—The field operations for the household survey are performed by the Bureau of the Census under specifications established by the Public Health Service. In accordance with these specifications the Bureau of the Census designs and selects the sample; conducts the field interviewing, acting as the collecting agent for the Public Health Service; and edits and codes the questionnaires. Tabulations are prepared by the Public Health Service using the Bureau of the Census electronic computers.

Estimating methods.—Each statistic produced by the survey—for example, the number of dental X-ray visits—is the result of two stages of ratio estimation. In the first of these, the factor is the ratio of the 1950 decennial population count to the 1950 estimated population in the U. S. National Health Survey's first-stage sample of PSU's. These factors are applied for some 50 color-residence classes.

Later, ratios of sample-produced estimates of the population to official Bureau of the Census figures for current population in about 60 age-sex-color classes are computed, and serve as second-stage factors for ratio estimating.

The effect of the ratio estimating process is to make the sample closely representative of the population by age, sex, color, and residence, thus reducing sampling variance.

As noted, each week's sample represents the population living during that week as well as characteristics of the population. Consolidation of samples over a time period, say a calendar quarter, produces estimates of average characteristics of the U. S. population for that calendar quarter.

For population statistics, such as the population used in obtaining rates of medical X-ray visits, figures for a specific calendar quarter are averages of estimates for all weeks of interviewing in that quarter. Similarly, population data for a year are averages of the four quarterly figures.

For statistics measuring the number of occurrences during a specified time period, such as the number of dental X-ray visits, a similar computational procedure is used, but the statistics have a different interpretation. For the X-ray visit items, the questionnaire asks for the respondent's experience over the three months prior to the week of interview. In such instances the es-

timated quarterly total for the statistic is obtained by averaging estimates for all weeks of interviewing in the quarter. The annual total is the sum of the four quarterly estimates. Thus, the experience of persons interviewed during a year—experience which actually occurred for each person in a 13-calendar-week period prior to the week of interview—is treated in analysis as though it measured the total of such experience occurring in the year. Such interpretation leads to no significant bias.

General Qualifications

Nonresponse.—Data were adjusted for nonresponse by a procedure which imputes to persons in a household which was not interviewed the characteristics of persons in households in the same segment which were interviewed. The total noninterview rate was 5 percent; 1 percent was refusal, and the remainder was primarily due to the failure to find any eligible household respondent after repeated trials.

The interview process.—The statistics presented in this report are based on replies secured in interviews of persons in the sampled households. Each person 17 years and over, available at the time of interview, was interviewed individually. Proxy respondents within the household were employed for children and for adults not available at the time of the interview, provided the respondent was closely related to the person about whom information was being obtained.

There are limitations to the accuracy of diagnostic and other information collected in household interviews. For diagnostic information, the household respondent can, at best, pass on to the interviewer only the information the physician has given to the family. For conditions not medically attended, diagnostic information is often no more than a description of symptoms. However, other types of facts such as those concerning the circumstances and consequences of illness or injury and the resulting action taken or sought by the individual can be obtained more accurately from household members than from any other source, since only the persons concerned are in a position to report all of this type of information.

Rounding of numbers.—The original tabulations on which the data in this report are based show all estimates to the nearest whole unit. All consolidations were made from the original tabulations using the estimates to the nearest unit. In the final published tables the figures are rounded to the nearest thousand, although they are not necessarily accurate to that detail. Derived statistics such as rates and percent distributions are computed after the estimates on which they are based have been rounded to the nearest thousand.

Population figures.—Some of the published tables include population figures for specified categories. Except for certain over-all totals by age, sex, and color, which are adjusted to independent estimates, these figures are based on the sample of households in the U. S. National Health Survey. They are given primarily for the purpose of providing denominators for rate computation, and for this purpose are more appropriate for use with the accompanying measures of health characteristics than other population data that may be available. In some instances they will permit users to re-

combine published data into classes more suitable to their specific needs. With the exception of the overall totals by age, sex, and color, mentioned above, the population figures may in some cases differ from corresponding figures (which are derived from different sources) published in reports of the Bureau of the Census. For population data for general use, see the official estimates presented in Bureau of the Census reports in the P-20, P-25, and P-60 series.

Reliability of Estimates

Since the estimates are based on a sample, they will differ somewhat from the figures that would have been obtained if a complete census had been taken using the same schedules, instructions, and interviewing personnel and procedures. As in any survey, the results are also subject to measurement error.

The standard error is primarily a measure of sampling variability, that is, the variations that might occur by chance because only a sample of the population is surveyed. As calculated for this report, the standard error also reflects part of the variation which arises in the measurement process. It does not include estimates of any biases which might lie in the data. The chances are about 68 out of 100 that an estimate from the sample would differ from a complete census by less than the standard error. The chances are about 95 out of 100 that the difference would be less than twice the standard error and about 99 out of 100 that it would be less than 2% times as large.

The relative standard error of an estimate is obtained by dividing the standard error of the estimate by the estimate itself, and is expressed as a percentage of the estimate. Included in this Appendix are charts from which the relative standard errors can be determined for estimates shown in the report. In order to derive relative errors which would be applicable to a wide variety of health statistics and which could be prepared at a moderate cost, a number of approximations were required. As a result, the charts provide an estimate of the approximate relative standard error rather than the precise error for any specific aggregate or percentage.

Three classes of statistics for the health survey are identified for purposes of estimating variances.

Narrow range.—This class consists of 1) statistics which estimate a population attribute, e.g., the number of persons in a particular income group, and (2) statistics for which the measure for a single individual for the period of reference is usually either 0 or 1, on occasion may take on the value 2, and very rarely, 3.

Medium range.—This class consists of other statistics for which the measure for a single individual for the period of reference will rarely lie outside the range 0 to 5.

Wide range.—This class consists of statistics for which the measure for a single individual for the period of reference frequently will range from 0 to a number in excess of 5, e.g., the number of days of restricted activity experienced during the year.

In addition to classifying variables according to whether they are narrow-, medium-, or wide-range, statistics in the survey are further defined as:

Type A.—Statistics on prevalence, and incidence data for which the period of reference in the questionnaire is 12 months.

- <u>Type B.—Incidence-type</u> statistics for which the period of reference in the questionnaire is two weeks.
- Type C.—Statistics on data, such as hospitalizations, for which the period of reference is six months.
- Type D.—Statistics on data, such as X-ray visits, for which the period of reference in the questionnaire is three months.

Only the charts on sampling error applicable to data contained in this report are presented. Those shown are charts for aggregates based on four calendar quarters of data collection.

General rules for determining relative sampling errors.—The "guide" on page 40, together with the following rules, will enable the reader to determine approximate relative standard errors from the charts for estimates presented in this report.

Rule 1. Estimates of aggregates: Approximate relative standard errors of estimates of aggregates, such as the number of persons with a given characteristic, or the number of X-ray visits are obtained from appropriate curves on page 41. The number of persons in the total U. S. population or in an age-sex-color class of the total population is adjusted to official Bureau of the Census figures and is not subject to sampling error.

Rule 2. Estimates of percentages in a percent distribution: Relative standard errors of percentages in a percent distribution of a total are obtained from appropriate curves on page 42. For values which do not fall on one of the curves presented in the chart.

visual interpolation will provide a satisfactory approximation.

Rule 3. Estimates of rates where the numerator is a subclass of the denominator: (Not required for statistics presented in this report.)

- Rule 4. Estimates of rates where the numerator is not a subclass of the denominator: This rule applies where a unit of the numerator often occurs more than once for any one unit in the denominator. For example, in the computation of the number of dental X-ray visits per 100 persons per year, several of the X-ray visits included in the numerator could be assigned to each 100 persons (one unit) in the denominator. Approximate relative standard errors for rates of this kind may be computed as follows:
 - (a) Where the denominator is the total U. S. population, or includes all persons in one or more of the age-sexcolor groups of the total population, the relative error of the rate is equivalent to the relative error of the numerator which can be obtained directly from the appropriate chart.
 - (b) In other cases, obtain the relative standard error of the numerator and of the denominator from the appropriate curve. Square each of these relative errors, add the resulting values, and extract the square root of the sum. This procedure will result in an upper bound, and often will overstate the error.

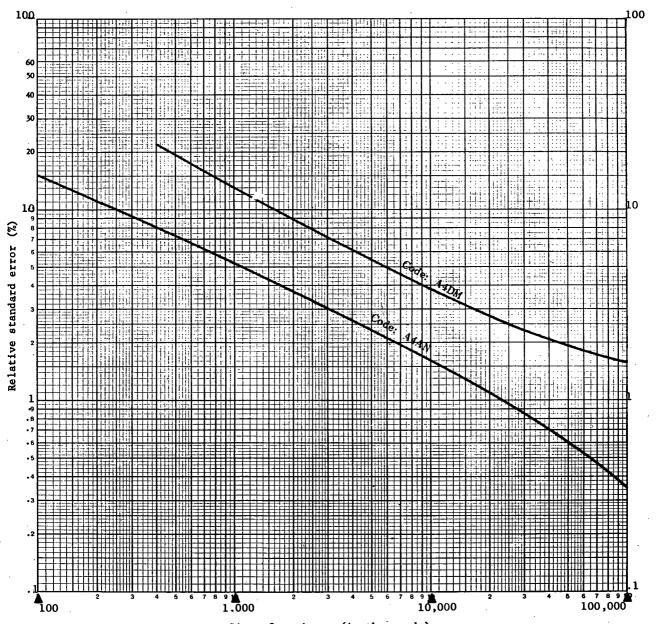

Guide to Use of Relative Standard Error Charts

The code shown below identifies the appropriate curve to be used in estimating the relative standard error of the statistic described. The four components of each code describe the statistic as follows: (1)

A = aggregate, P = percentage; (2) the number of calendar quarters of data collection; (3) the type of the statistic as described on page 38; and (4) the range of the statistic as described on page 38.

Statistic		Use:	
	Rule	Code on	page
Number of: Persons, by residence, region, income or education	, 1	A4AN	41
Persons in the U. S. population, or total number of persons in any age-sex-color category	Not subjec	ct to sampling error	
X-ray visits	1	A4DM	41
Percentage distribution of: X-ray visits	2	P4DN-M	42
X-ray visits per 100 persons: In the total U. S. population or in any age-sex-color group of the total U. S.			
population	4(a)	A4DM	41
In any other population group	4(b)	Numer.: A4DM Denom.: A4AN	41

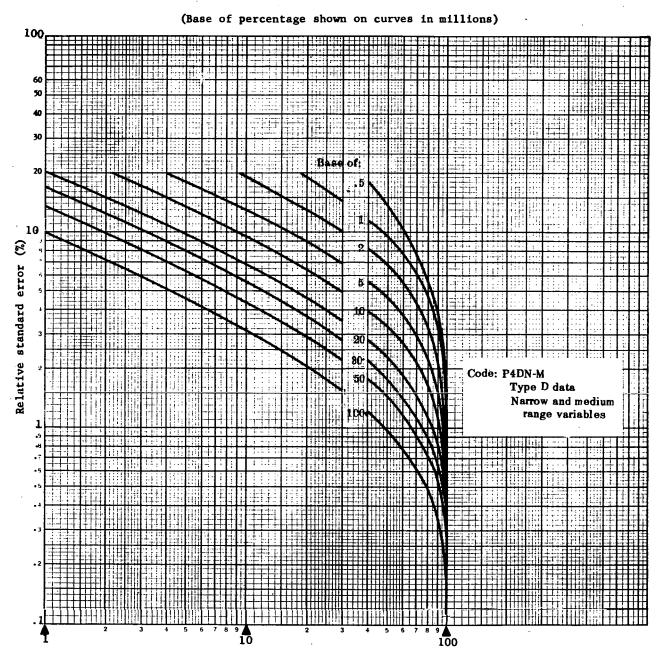

Relative standard errors for aggregates based on four quarters of data collection for type A, Narrow range, and type D, Medium range data

Size of estimate (in thousands)

Example of use of chart: An aggregate of 1,000,000 (on scale at bottom of chart) for a Medium range type D statistic (code: A4DM) has a relative standard error of 13.2 percent, read from scale at left side of chart, or a standard error of 132,000 (13.2 percent of 1,000,000).

Relative standard errors for percentages based on four quarters of data collection for type D data, Narrow and Medium range

Estimated percentage

Example of use of chart: An estimate of 20 percent (on scale at bottom of chart) based on an estimate of 10,000,000 has a relative standard error of 6.4 percent (read from the scale at the left side of the chart), the point at which the curve for a base of 10,000,000 intersects the vertical line for 20 percent. The standard error in percentage points is equal to 20 percent X 6.4 percent or 1.3 percentage points.

APPENDIX II

DEFINITIONS OF CERTAIN TERMS USED IN THIS REPORT

Terms Relating to X-rays

X-ray visit.—An X-ray visit is defined as a visit by a person to a physician's office, dentist's office, hospital, mobile X-ray unit, Public Health Department, etc., during the course of which X-ray equipment is used for diagnosis or treatment. X-ray includes X-ray film photography and X-ray emission for treatment and fluoroscopy, but excludes the use of radioisotopes. Only one visit is counted each time the person is x-rayed, regardless of the number of X-ray films exposed or the number of ports used. However, statistics are collected for each of the separate areas of the body toward which X-rays have been emitted (see below).

An X-ray visit is counted each time the person is x-rayed during the reference period. Hence, one person may be included in the statistics more than once. However, if several areas of the body are x-rayed during a single visit, only one X-ray visit is recorded. The term X-ray visit is used synonymously with "person-" event in other National Health Survey statistics, e.g., person-day.

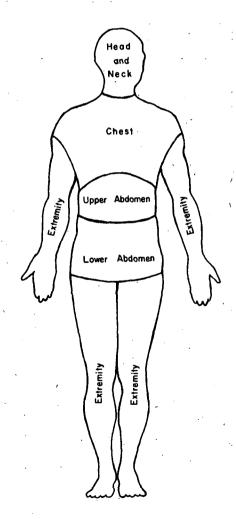

Statistics are prepared separately for dental X-ray visits and medical X-ray visits, i.e., other than dental. A dental X-ray visit is defined as an X-ray usually taken in a dentist's office for the primary purpose of studying the condition or formation of the teeth. If an X-ray of the teeth or jaw is taken in a hospital or clinic primarily for dental purposes, it is counted as a dental X-ray.

Place of X-ray.—The place of X-ray is a classification of the types of places at which an X-ray visit (other than dental) took place. Place of X-ray is not recorded for dental X-ray visits. The definitions of the three categories are as follows:

- Hospital is defined as the place at which X-rays were received while an inpatient in the hospital and also X-rays received as an outpatient at a hospital clinic.
- Doctor's office is defined as the office of any doctor who has his own X-ray equipment, or the office of a radiologist. "Doctor's office" also includes clinics run by a group of doctors if the clinic provides X-ray services.
- Other is defined as places other than hospitals or doctors' offices at which X-ray services are provided. For example, such places include schools, mobile units, Public Health Departments, etc.

Type of service.—X-ray service is classified as diagnosis or treatment. Diagnosis is defined as X-rays for checkup or examination using X-ray or fluoroscopic procedures to determine the presence, absence, or state of a disease or condition. X-rays for treatment are X-rays used in treating a condition which has already been diagnosed.

Body areas.—For each X-ray other than dental, the area of the body to which the X-rays are directed is classified in one of six categories in addition to an "unknown" group, shown in the accompanying chart.

The six categories are defined as follows:

- Head and neck is defined as that portion of the body, exclusive of skin covering, above the trunk.
- 2. <u>Chest</u> is defined as that portion of the trunk above the diaphragm including the shoulder.
- Upper abdomen is defined as that portion of the body between the diaphragm and the transverse colon.
- Lower abdomen is defined as the remainder of the trunk including the hip.
- Extremities are defined as the arms exclusive of the shoulders and the legs exclusive of the hip.
- Skin is defined as the outer covering of the body made up of an epithelial layer, the scarf skin, and the true skin.

Demographic, Social, and Economic Terms

Age.—The age recorded for each person is the age at last birthday. Age is recorded in single years and grouped in a variety of distributions depending upon the purpose of the table.

Race.—In this report, the population has been subdivided into two groups according to race, "White" and "Nonwhite." "Nonwhite" includes Negro, American Indian, Chinese, Japanese, and so forth. Mexican persons are included with "White" unless definitely known to be Indian or other nonwhite race.

Family income.—Each member of a family is classified according to the total income of the family of which he is a member. Within the household all persons related to each other by blood, marriage, or adoption constitute a family. Unrelated individuals are classified according to their own income.

The income recorded is the total of all income received by members of the family (or by an unrelated individual) in the 12-month period ending with the week of interview. Income from all sources is included, e.g., wages, salaries, rents from property, pensions, help from relatives, and so forth.

Education of family head.—Each member of a family is classified according to the education of the head of the family of which he is a member. Within the household all persons related to each other by blood, marriage, or adoption constitute a family. Unrelated individuals are classified according to their own education.

The categories of educational status show the highest grade of school completed. Only grades completed in regular schools, where persons are given a formal education, are included. A "regular" school is one which advances a person toward an elementary or high school diploma, or a college, university, or professional school degree. Thus, education in vocational, trade, or business schools outside the regular school system is not counted in determining the highest grade of school completed.

Location of Residence Terms

<u>Urban residence.</u>—The definition of urban areas used in the U. S. National Health Survey is the same as

that used in the 1950 Census. According to this definition, the urban population comprises all persons living in (a) places of 2,500 inhabitants or more incorporated as cities, boroughs, and villages; (b) incorporated towns of 2,500 inhabitants or more except in New England, New York, and Wisconsin, where "Towns" are simply minor civil divisions of counties; (c) the densely settled urban fringe, including both incorporated and unincorporated areas around cities of 50,000 or more; and (d) unincorporated places of 2,500 inhabitants or more outside any urban fringe.

In this report, the urban population has been subdivided into those living ''Inside urbanized areas'' and those living in ''Other urban places.''

Inside urbanized areas.—Following the definition used in the 1950 Census, the population in urbanized areas comprises all persons living in (a) cities of 50,000 inhabitants or more in 1940 or according to a special census taken between 1940 and 1950; and (b) the densely settled urban fringe, including both incorporated and unincorporated areas, surrounding these cities.

Other urban places.—The remaining urban population not classified as living 'Inside urbanized areas' is classified as living in 'Other urban places."

<u>Rural residence</u>.—The remaining population not classified as "Urban" is classified as "Rural." In this report the rural population has been subdivided into "Rural farm" and "Rural nonfarm."

Rural farm, -- All rural residents living on farms are classified as "Rural farm." In deciding whether members of a household reside on a farm or ranch, the statement of the household respondent that the house is on a farm or ranch is accepted, with the following exception. A house occupied by persons who pay cash rent for the house and yard only is not counted as a farm or ranch even though the surrounding area is farm land. This special case does not cover: (1) the living quarters of a tenant farmer who rents farm land as well as house and yard; (2) the quarters of a hired hand who receives living quarters on a farm as part of his compensation; or (3) separate living quarters inside a structure which is classified as on a farm. In all these cases the living quarters are counted as on a farm.

<u>Rural nonfarm</u>.—The remaining rural population not classified as "Rural farm" is classified as "Rural nonfarm."

Region and geographic division.—For the purposes of classifying the population by geographic area of residence, the U. S. National Health Survey uses the same grouping of states used by the Bureau of the Census and many other agencies. The major regions and geographic divisions are:

Region and Division

APPENDIX IV

PRETESTING THE X-RAY QUESTIONS

Introduction

During the 12-month period from July 1960-June 1961 five new questions and a new table were added to the Health Interview Survey questionnaire to obtain information about the volume of medical and dental X-ray visits made by the civilian, noninstitutional population of the United States. A pilot study was conducted in Hagerstown, Maryland, in October 1959 to test the design of the questions. A second pretest with revised probe questions was conducted in Washington, D. C., and vicinity in January 1960.

Preliminary study by the National Health Survey and the Bureau of the Census indicated the desirability of using a "record-check" type of pretest. A "record-check" pretest, as the name implies, is one in which the actual experience of members of the sample for the reference period has been obtained from records of the specific events. The responses obtained during the household interview are then compared with the data from records and degree of match noted. In the case of the Hagerstown and Washington pilot studies, the objectives were to test the effectiveness of the design of the probe questions, and especially, to determine the optimum period of memory recall of X-ray experience.

HAGERSTOWN, MARYLAND SAMPLE SURVEY, OCTOBER 1959

Planning and Conducting the Survey

Because of the nature of the X-ray questions proposed for addition to the regular NHS questionnaire during July 1960-June 1961, it was decided to pretest the questions among a sample of households in which at least one member had had X-ray experience during the previous 12 months. A sample of names and addresses was obtained from the records of certain X-ray facilities in Hagerstown. These facilities included dentists, physicians, the X-ray department of the hospital, the X-ray unit of a private clinic, and the chest X-ray center of the city health department. At the time the names and addresses were recorded, the date, place of visit, type of X-ray, and part of body x-rayed were also recorded.

Interviewers were not informed that X-ray records were available, nor were they given the names of persons at the addresses where interviews were to be conducted. This was done partly to safeguard the confidentiality of the information, but primarily to avoid biasing the interviewers through a foreknowledge of X-ray experience of persons in the household.

In order to simulate the length and complexity of the customary interviewing situation, the NHS questionnaire in use between July 1959 and June 1960 was used in the pretest. The X-ray questions and table (shown in table I) replaced the health insurance probe questions, hospital insurance coverage questions in table II, hospitalization, and table A, accidents. Questionnaires and interviewer instructions were prepared, and selection and training of six regularly employed NHS interviewers was undertaken.

The survey was conducted during the week of October 26, 1959. Observers from the National Health Survey and the Bureau of the Census accompanied each of the interviewers to find out the reactions of both interviewer and respondent to the new questions and answers to these questions.

A total of 92 completed household interviews were obtained from among the X-ray record cases: 26 dental X-ray cases and 66 medical X-ray cases. Table A summarizes the findings of the study with respect to degree of 'match' with the record source data.

The definition of match used in this pretest was more rigorous than the categories of classification used later for the processing of the regular NHS questionnaire for the period July 1960-June 1961. The part of the body x-rayed was considered a match only if the same specific part mentioned in the interview was noted in the record. For example, an interview report of an X-ray of the back was not considered a match if the record source specified a chest X-ray. During the regular survey, six body areas were used to classify part of the body and a glossary of terms was prepared of acceptable terms for each of the six areas. Therefore, it is reasonable to expect that the percentage of "matched" cases, shown above, would have been higher using less rigid rules.

WASHINGTON, D. C. SAMPLE SURVEY, JANUARY 1960

Planning and Conducting the Survey

On the basis of the results of the Hagerstown study, the format of the X-ray probe questions was redesigned, and planning began for a further pretest in a sample population in Washington, D. C., and immediate vicinity, in January 1960. Changes in the probe questions were in the direction of improving match percentages for medical X-ray visits which were quite low in the Hagerstown study. For example, treatment X-rays were relatively poorly reported; to improve this percentage a probe was specifically directed toward treat-

[&]quot;Match" was defined as a report in the interview of the same part of the body and type of procedure as that shown in the record. The date reported by the respondent must have been within the limits of the recall period to be accepted as a "Match."

ment in a question on a single part of the body (see tables I and II). Three columns were added to the hospitalization table to inquire about X-rays during each period of hospitalization recorded.

The memory recall period was reduced from 12 to 3 months. In addition, a number of cases were included in the sample who had X-rays within two weeks of the interview week, in order to test whether a two-week-recall period would produce better results than a three-month period.

Cases were selected to include a group of hospital inpatients and outpatients, radiologist's patients, and mobile X-ray unit cases. Interviewing was conducted from January 18-23, and 169 completed interviews were obtained (see below).

Results of the Survey

The percentages of matched cases were higher in this study, both for the two-week-recall and three-month-recall periods. The criteria for á match were essentially the same as for the Hagerstown pretest; that is, a report of an X-ray of the same part of the body but with the added feature of a report for the same month of visit as that shown on the record. Table B shows results of this study.

For some types of X-ray visits it appears that a two-week-reference period would be better than a longer period, as judged from the match rates. However, match rates alone fail to reveal two other factors that must be considered in conducting a population survey for the purpose of producing estimates of the aggregate number of visits. First, some persons who have had X-rays in the past two weeks may be in a hospital at the time an interviewer calls at the household. This results in a higher than normal noninterview rate, with consequent loss of data. Second, the use of a two-week recall period appreciably increases the relative sampling error as compared with a three-month-recall

period when producing annual estimates of the aggregate number of visits. The problems of noninterview, together with the decreased volume of data ruled against the use of a two-week reference period for this topic.

It will be noted that although the over-all level of reporting of medical X-ray visits for three-month recall was at about the same level in Hagerstown and in Washington (73 percent), the Washington study was heavily weighted with proxy respondents. For self responses and also for proxy responses the Washington test produced better match rates. If one applies the Washington pretest match rates to the self-proxy respondent ratio in the National Health Interview Survey, this yields about a 77 percent expected rate of match on the basis of the matching criteria used in the pretest.

There is evidence that a match rate of 73 percent on the pretest (or 77 percent adjusted for respondent differences) is not an indication of the extent of reporting of the gross volume of X-ray visits, but rather indicates the precision with which respondents can reproduce the circumstances of visits to a degree that they can be unmistakably identified with visits in a record source. There were, for the 169 persons in the pretest, 406 visits in the medical record. For these same persons 438 visits were reported by interview but only 73 percent "matched" the record. In terms of gross volume of visits the record and the interview are not highly discrepant. It is quite possible that some persons in the pretest had X-ray visits at locations outside of the sources of the records, and reported such visits on interview. It is also possible that some respondents may have reported on interview X-ray visits which were prior to the three-month-reference period. Whatever the reason, the number of visits reported equaled or exceeded the number in the record for all classes of patients except the "treatment" group. For this group there were 169 X-ray visits in the records, 139 reported on interview, and 81 (48 percent) matched by the criteria employed.

Table B. Summary of results of Washington pretest

	Number of	Percent of visits matched		
Type of case	persons in 3-month period	2-week recall	3-month recall	
Total	169	69	73	
HospitalOutpatient	115 23	70 75	.70 69	
TreatmentInpatientInpatient	10 82	100 67	48 72	
Radiologist Mobile X-ray unit	40 14	67 60	80 79	
Self respondent	79	84	80	
HospitalOutpatient	49 14	90 100	78 82	
TreatmentInpatient	6 29	100	60	
Radiologist	29	86 50 S	79 84	
Mobile X-ray unit	8	100	88	
Proxy respondent	90	66	70	
Hospital	66	65	70	
Outpatient	. 9	33	57	
Treatment	4	100	32	
InpatientRadiologist	53	65	75	
Mobile X-ray unit	18 6	100 · 33	74 67	

Although all of the factors involved in underreporting, overreporting, and mismatching could not be identified from the pretests, it was concluded that the precision of reporting was not less than shown by the percentages in table B and that the gross volume of reporting was reasonably complete for all classes of patients except those receiving treatment, for whom the volume of visits might be underreported by about 20 percent.

On the basis of these results, the X-ray probe questions and table X, shown in this Appendix IV, were included in the questionnaire used nationally during July 1960-June 1961. Minor changes were made in the form of the questions and table. The three-month-recall period was used, but the additional columns in the hospitalization table were omitted.

Table I. X-ray Questions: Hagerstown Pretest

		Col. (1)	Col. (2)
