COOPERATION OF THE BUREAU OF THE CENSUS

Under the legislation establishing the National Health Survey, the Public Health Service is authorized to use, insofar as possible, the services or facilities of other Federal, State, or private agencies.

In accordance with specifications established by the National Health Survey, the Bureau of the Census, under a contractual arrangement, participates in most aspects of survey planning, selects the sample, collects the data, and carries out certain parts of the statistical processing.

IN THIS REPORT data are presented on disability, illness, and the use of medical services for persons in the labor force, according to occupation. In the detailed tables, information on the health of persons in the labor force is shown by the demographic characteristics of the 11 occupational groups summarized from the code categories in the Classified Index of Occupations and Industries used for the 1960 Decennial Census.

For purposes of analysis and graphic presentation, these 11 groups have been further condensed into 4 major occupational categories. White-collar workers include professional, technical, managerial, clerical, sales, and kindred workers; blue-collar workers include craftsmen, operatives, and nonfarm laborers; service workers include private household and all other types of service workers; and farm workers include farmers, farm managers, and farm laborers.

The basic population group in this report is the labor force, defined in the Health Interview Survey as persons aged 17 years and over who worked at or had a job or business, were looking for work, or were on layoff from work during the 2-week period prior to the week of interview. However, when a certain measure of illness or disability, such as days of work loss, can be applied only to the currently employed or is of particular interest in relation to employment status, data for the currently employed population are shown. Currently employed persons are those in the labor force who worked at or had a job during the 2-week period prior to the week of interview.

In general, data in this report indicate that farmers and farm laborers have a higher rate of chronic illness and associated disability than persons in nonfarm occupations. Farm workers spend less money for health services and are least prepared to meet health expenses by means of hospital and surgical insurance than any other occupational group.

SELECTED HEALTH CHARACTERISTICS BY OCCUPATION

Geraldine A. Gleeson, Division of Health Interview Statistics

SELECTED FINDINGS

Based on data collected in the Health Interview Survey during the period July 1961-June 1963, approximately 7.3 percent of the 71.5 million persons in the labor force had chronic limitations affecting their ability to work. By occupational status, this percentage with chronic disability ranged from 3.7 percent among professional, technical, and kindred workers to 19.0 percent among farmers and farm managers. Regardless of demographic characteristics, the rate of chronic limitation was lowest among white-collar workers and became progressively higher among bluecollar, service, and farm workers.

The pattern of temporary disability, in terms of days of restricted activity—that is, days on which persons had to cut down on their usual activities—was quite similar to that for chronic limitation. The number of days of work loss increased appreciably with age for all occupational groups, with the highest rate, 11.5 days per currently employed person per year, occurring among farm workers aged 45 years and over.

Even though the rates of acute and chronic conditions among working persons were much lower than for other segments of the population, illness and injury among persons in the labor force were still important causes of absenteeism. Some of the leading causes of chronic limitation among persons in the labor force were heart conditions, arthritis or rheumatism, and orthopedic impairments. Approximately 20 out of every 1,000 white-collar workers were limited in ability to work or to carry on other activities because of orthopedic impairment, as compared with 52 per 1,000 among farm workers. The high proportion of persons aged 45 years and over among farmers accounted for a part of this difference. The rates of heart conditions and arthritis and rheumatism causing activity limitation were also higher for farm workers than for other occupational groups.

The rates of acute conditions of all types and of acute respiratory conditions were higher among white-collar and service workers than for blue-collar and farm workers. On the other hand, the rate of persons injured was significantly higher among blue-collar and farm workers. In both of these groups, accidents while at work were responsible for a high proportion of the injuries. Of the 346.8 persons injured per 1,000 blue-collar workers, 206.7 were injured while at work; of the 294.7 injured per 1,000 farm workers, 175.7 were injured in work accidents.

Approximately 6 million discharges from short-stay hospitals (84.2 per 1,000 persons in the labor force) occurred during an average year. This number represented about 27 percent of the discharges for the entire population of the United States. The rate of hospital discharges was highest among service workers (98.5 discharges per 1,000) and lowest among farm workers (64.8 per 1,000). The length of hospital stay was slightly higher among blue-collar and farm workers than for whitecollar and service workers. This differential may have been related to the high rates of work injuries among blue-collar and farm workers.

In the four major occupational categories, 84.5 percent of the white-collar workers had hospital insurance coverage, as compared with 76.6 percent of the blue-collar workers, 64.8 percent of the service workers, and 42.0 percent of farm workers. The rate of health insurance coverage was particularly low among farmers, farm laborers, and private household workers—occupational groups which have little opportunity to obtain insurance through organized employee groups.

Among persons in the labor force the average expenditure per year was \$142 for medical and dental expenses, including expenses paid through insurance benefits; the average expenditure among persons in the total population was \$129. Total expenses ranged from \$84 for the farm worker to \$169 for the whitecollar worker. The highest proportion of expenses in each of the occupational groups was for the payment of doctor bills. With the exception of dental expenses, all types of health expenses increased with advancing age.

SOURCE AND DESCRIPTION OF THE DATA

During July 1961-June 1963, information was collected on the occupational status of persons included in the Health Interview Survey sample population. The inclusion of this item on the questionnaire used in the health interviews made it possible to derive statistics pertaining to health characteristics of various occupational groups in the labor force of the United States.

The information contained in this report is based on data collected in a continuous nationwide survey conducted by household interview. Each week a probability sample of households is interviewed to obtain information relating to the health characteristics of each member of the household.

The Survey is limited to the civilian, noninstitutional population of the United States.

For some kinds of information, such as the incidence of acute conditions, the effect of this restriction on the data is negligible; for other types, such as the prevalence of specific chronic conditions for which the rate of institutionalization is relatively high, a considerable underestimation may result. Another general qualification of the Survey is that the collected information refers only to persons who were alive at the time of interview. This exclusion of information for persons who died prior to interview tends to somewhat reduce certain types of estimates. Hospital data, for example, provide information on the hospital experience of the population but do not assess the total amount of care provided by hospital facilities during a given year.

In the Health Interview Survey, interviews are conducted during each year in approximately 42,000 households composed of 134,000 persons. The estimates in this report that have been derived from 2 years of data collection are based on approximately twice the number of households and persons shown above. Since the estimates from interview data are based on a sample, they will differ somewhat from figures that would have been obtained if a complete census had been taken using the same procedures.

Most of the estimates shown are based on 2 years of data collection, July 1961-June 1963. However, for two of the health-related items included in the report, health insurance coverage and personal health expenses, information was not collected during the entire 2year period. For these items, it was necessary to present data based on shorter periods of collection. Comparative estimates shown throughout the report for the total population of the United States are derived from statistics presented in other reports and from unpublished data.

A description of the design of the Survey, the methods of estimation, and the general qualifications of data obtained from surveys is presented in Appendix I. As previously mentioned, the estimates shown in this report are based on a sample of the population and are therefore subject to sampling error. Although most of these errors are of relatively low magnitude, where an estimated number or the numerator or denominator of a rate or percentage is small, the sampling error may be high. For this reason, particular attention should be directed to the section in Appendix I entitled "Reliability of Estimates." Charts of relative sampling errors and instructions for their use are also presented in Appendix I.

Certain terms used in the report are defined in Appendix II. An illustration of the questionnaire used in the Survey during the period July 1962-June 1963 can be found in *Vital and Health Statistics*, "Current Estimates," Series 10, No. 5.

THE LABOR FORCE

Information on occupational status was obtained during the data-collection period July 1961-June 1963 for all members of the labor force. Included in the labor force, as defined in the Health Interview Survey, are all persons aged 17 years and over who worked at or had a job or business, were looking for work, or were on layoff from work during the 2-week period prior to the week of interview. Those who worked or had a job at any time during this period are further defined as currently employed persons. The others, classified as looking for work or on layoff during the period, are considered unemployed.

Data presented in this report are not intended to be official labor force estimates. The classification of the labor force into appropriate groups for the study of comparative illness and disability rates required procedures for describing employment and occupational status which resulted in estimates similar to, but not precisely the same as, official data released by the U.S. Bureau of Labor Statistics. For example, this report includes only persons 17 years of age or over, whereas official labor force estimates include persons aged 14 years and over. Also, the Health Interview Survey employs a 2-week reference period-that is, a person who worked at any time during a 2-week period is included among the currently employed-whereas official employment data are based on a 1-week reference period. Furthermore, official figures include unpaid family workers only if they worked 15 or more hours during the week, while the Survey does not distinguish between persons who work more than or less than 15 hours per week.

In this report, persons in the labor force and in the currently employed population are classified by occupation to code categories in the Classified Index of Occupations and Industries used for the 1960 Decennial Census. The 11 summary groups (and a residual group consisting of new workers and persons of unknown occupational status) shown in the detailed tables represent a further adaptation of the occupation classification system used in 1960 census reports. For purposes of analysis and graphic presentation, these groups were even further condensed into four major categories often used in the presentation of labor statistics:

Occupational category Census code

White-collar workers

Professional, technical, and	
kindred workers	000-195
Managers, officials, and	
proprietors, except farm-	250-285, R
Clerical and kindred	
workers	301-360, Y, Z

Blue-collar workers

Craftsmen, foremen, and	
kindred workers	401-545, Q
Operatives and kindred	
workers	601-721, T, W
Laborers, except farm and	
mine	960-973, X

Service workers

Private household workers-	801-803, P
Other service workers	810-890

Farm workers

Farmers and farm	
managers	222, N
Farm laborers and foremen-	901, 905, U, V

Because the data included here were collected weekly throughout the year and cumulated for the year, the estimates refer to average employment and unemployment during July 1961-June 1963. Official estimates, on the other hand, are obtained for discrete points of time during the year. (For official labor force estimates and definitions, see *Employment and Earnings*, published by the Bureau of Labor Statistics.) Since the major emphasis in this report is on the comparative amount of illness and disability in the occupational categories, the labor force, rather than the currently employed population, is considered the basic population group. However, when a certain measure of illness or disability—such as time lost from work—can be applied only to the currently employed or is of particular interest in relation to employment status, data for the

currently employed population are shown. Material relating to the comparative amounts of disability among the currently employed and the currently unemployed populations, by occupation and by selected demographic characteristics, can be found in *Vital and Health Statistics*, "Disability Among Persons in the Labor Force, by Employment Status," Series 10, No. 7.

In the interpretation of the differences in the health characteristics of the occupational groups, it is helpful to have some knowledge of the population composition within the several groups. Table A shows the distribution of the four major occupational classes by such demographic characteristics as sex, age, color, family income, and education of the individual.

About 24.8 million persons, or one-third of the estimated 71.5 million persons in the labor force, were females. The greatest concentrations of women occurred among whitecollar workers, where they represented 44.1 percent of the total number, and among service workers, where they represented 65.5 percent of the total.

About 39.9 percent of the persons in the labor force were 45 years of age and over. Among service and farm workers the proportion of older persons was considerably higher; 45.3 percent of the service workers and 51.9 percent of the farm workers were aged 45 years or over. While nonwhite workers constituted about 11.4 percent of the total labor force, the proportion in the four major occupational classes ranged from 4.2 percent among white-collar workers to 30.0 percent among service workers.

The amount of family income and the number of years of formal education received were highly correlated with occupational level. The proportion of persons with income less than \$4,000 ranged from 15.1 percent among whitecollar workers to 60.1 percent among farm workers, while the percentage with less than 9 years of formal education equaled 98.9 percent in the former group, as compared with 54.9 percent in the latter.

Another factor which is of interest in the study of health measures among the occupational classes is the degree of stability within classes. To obtain a gross measure of this characteristic, all persons 20 years of age and over who reported an occupation were asked if they had been doing this kind of work (implied from the occupation) for the past 3 years. From the estimates derived from responses to this question, it was determined that approximately 75 percent of the white-collar and blue-collar workers aged 20 years and over had been in the same or a similar type of occupation for at least 3 years, as compared with 67 percent of the service workers and 86 percent of the farm workers. In the more detailed occupational groups, the percentage with

Table B. Percent distribution of persons aged 17+ years in the labor force, by class of worker according to occupational category: United States, July 1961-June 1963

at least 3 years in the same occupation ranged from a low of 62 percent among laborers (exclusive of farm and mine) to 93 percent among farmers or farm managers.

Table B shows the distribution of the major occupational groups by class of worker. About 88.4 percent of the blue-collar workers were classified as private-paid. Approximately 64.8 percent of the white-collar workers were private-paid; 18.1 percent were employed by Federal. State, or local governments; and 16.1 percent were self-employed. About three-fourths of the service workers were private-paid, and 6.7 percent were self-employed. The 15.6 percent of the service workers employed by government (other than Federal) was composed principally of protective service workers such as firemen and policemen. The farm workers classified as private-paid (35.1 percent) were for the most part farm laborers, and a high proportion of the 59.6 percent reported as selfemployed were farm owners.

DISABILITY IN THE LABOR FORCE

In the Health Interview Survey two aspects of disability due to illness or injury are measured: (1) long-term disability due to chronic disease, described in terms of a person's inability to carry on all or part of his regular activities, and (2) short periods of disability measured in terms of days of restricted activity, bed disability, and work loss attributable to either chronic or acute illness. Both of these measures are appropriate to use in determining the relative amount of disability in occupational groups. The one, activity limitation, estimates the number of persons who have been able to remain in the labor force even though they are limited in the amount or kind of work they can do or are limited in a lesser capacity. The rate of work loss in the currently employed segment of the occupational groups provides an estimate of the economic toll due to days of work absence associated with chronic illness or with conditions of shorter duration (acute conditions).

Long-Term Disability

For each person for whom at least one chronic condition was reported during the interview, the respondent was shown a card appropriate to the person's major activity and was asked which statement on the card best fitted the activity status of the person. For all males and for females who reported their major activity as working, these statements were as follows:

- 1. Not able to work at all
- 2. Able to work, but limited in amount of work or kind of work
- 3. Able to work, but limited in kind or amount of other activities
- 4. Not limited in any of these ways

In general, persons in the labor force were classified according to their ability to work. Females who had worked at some time during the 2-week period prior to interview yet had reported their major activity as keeping house were classified according to their activity status in relation to keeping house. However, it is unlikely that many women who kept house and were also employed outside the home, either part-time or seasonally, would have been limited in their ability to carry on either activity.

Approximately 37,448,000 persons, 52.4 percent of the 71,485,000 persons in the labor force, had one or more chronic conditions. Included in this percentage were 7.3 percent who were either limited in their ability to work or were unable to work (even though they were still in the labor force) and 3.7 percent who were limited in other activities, such as participation in recreational or social events.

Since in the various occupational groups the percentage of persons with limitation in ability to work is the most meaningful measure of the relative amount of disability in these groups, estimates of the distribution of persons in the labor force by limitation status are shown in tables 1-11 according to a number of demographic characteristics. In general, these tables show that regardless of demographic characteristics the highest rates of chronic limitation were found among persons engaged in farm work (owners, managers, and laborers) and among private household workers.

When the four broad occupational categories were considered according to age, sex, or color, the percentage of persons limited in working ability was lowest among white-collar workers. This proportion increased consistently among blue-collar and service workers, and it was highest among farm workers (table C). As in other segments of the population, the proportion of limited persons in the labor force increased with advancing age. The percentage of males limited in their ability to work exceeded the percentage of females so limited. These relationships were consistent for all four major occupational categories.

The proportion of nonwhite persons in the labor force who were limited in their working ability was slightly higher than the proportion of limited working persons among the white population. However, the difference in the amount of limitation by color was not significant for any of the four occupational categories (table C).

A high percentage of limitation in ability to work was associated with low income and with a low level of educational attainment (fig. 1). In each of the occupational categories the proportion of persons with limited ability to work became less as the amount of family income increased.

There is little doubt that the high rates of chronic disability among persons living in families with income less than \$4,000 are responsible to some degree for the reduced income in this group. Rates of chronic illness not causing activity limitation are greatest among persons in high income groups. Only among persons whose chronic illness is associated with limitation of activity is there an inverse relationship of the prevalence of chronic illness and the amount of family income (Series 10, No. 9).

Because educational attainment is highly correlated with level of family income, in the

educational groups the general pattern of limitation in ability to work was quite similar to that shown for family income. However, in the lowest educational group, less than 9 years of formal schooling, there was a notable exception to the usual trend. The un-

usually high rate of disability among whitecollar workers with less than 9 years of schooling was due to the large proportion of persons aged 45 years and over included in this group. As shown in table D, approximately 75 percent of the white-collar workers with less than

Table D.	Percent of white-collar workers aged 45+ years, by educational level: United
	States, July 1961-June 1963

Educational level	White-co	White-collar workers			
Educational level	Total	45 1 yea	rs		
	Numbe	mber Pei			
Under 9 years 9-12 years 13+ years	2,729,000 16,049,000 11,652,000	2,039,000 5,767,000 4,143,000	74.7 35.9 35.6		

9 years of education were aged 45 years or over, as compared with 36 percent among those with 9 or more years of schooling. Contributing to the high rate of disability among whitecollar workers of low educational status were older persons classified as proprietors, salesmen, or clerical workers who either went into business or were employed before present educational standards for employment had been established.

Disability Days

The estimated number of days of restricted activity, bed disability, and work loss among persons in the labor force was derived from responses to questions in table I of the questionnaire used in the Survey. For each illness or injury reported in response to the illness-recall questions, additional questions were asked to elicit the number of disability days during the 2-week period prior to the week of interview which could be attributed to each of the conditions.

From responses to these questions, estimates of person-days of short-term disability were derived. If a day of disability was attributable to more than one illness, the day was counted as only 1 person-day of disability.

Annual estimates can be derived by appropriately weighting the 2-week estimates of disability. Furthermore, the continuous sampling throughout the year in the Survey removes seasonal bias from annual estimates for all items for which the 2-week-recall period is used.

Days of Restricted Activity and Bed Disability

Based on data collected during the period July 1961-June 1963, persons in the labor force annually accounted for about 887.5 million days of restricted activity. This represented approximately 30 percent of the 2,957.4 million days estimated for persons of all ages. When the estimate was limited to persons aged 17 years and over, the labor force contributed 40 percent of the total 2,237.5 million days.

The number of days of restricted activity per year per person in the labor force was 12.4 days, as compared with 19.1 days for all persons aged 17 years and over. While the rate of restricted activity was only slightly lower for currently employed persons than for all persons in the labor force, the rate of restricted activity, as well as the rate of bed disability, was considerably lower for the currently employed (11.7 days per person) than for the unemployed (21.6 days per person). (See table 2, Series 10, No. 7.)

In the occupational groups, the rate of days of restricted activity was notably higher among farmers, including farm managers (18.4 days per person per year), and among private household workers (19.1 days) than for any of the other groups (tables 12 and 13). The high rates of disability for these two groups were consistent for males and females, although the numbers of female farmers and farm managers and of male private household workers were quite small (tables 14 and 15). However, when these groups were considered by age, it was apparent that the excessive rate of disability among farmers was attributable to the large number of farmers aged 45 years and over (table 13). In comparison with other occupational groups, in which a high proportion of workers retired with advancing age, farmers tended to remain in the labor force. Private household workers had a high rate of restricted activity regardless of age. It is possible that persons with limitations in their ability to work sought this kind of employment because it offered more flexibility in job attendance.

The rates of bed disability for the occupational groups did not vary to the same extent as the days of restricted activity. Among farmers, particularly, the rate of bed disability was equivalent to that for other occupational groups. A possible explanation of the pattern of disability among farmers is related to the kinds of illnesses they experienced. Farmers, a group including a large proportion of older persons, had the highest rate of chronic limitation, much of which was associated with conditions such as arthritis and orthopedic impairment. They also had the lowest rate of acute illness. This may have resulted in many days of restricted activity but few days of bed disability, which are usually associated with acute episodes of illness.

Nonwhite persons who were currently employed had, on the average, 3.2 more days of restricted activity and 1.8 more days of bed disability than did white persons. Occupational groups in which the rates were markedly higher among nonwhite persons include farmers and farm managers; craftsmen, foremen, and kindred workers; private household workers; and all classes of laborers (tables 16 and 17).

Days of Work Loss

To insure that information on absence from work was obtained for both full-time and part-time workers in the population, the question regarding work loss was asked for all persons 17 years of age and over. However, in the processing of the data this item was edited to include only the days reported for the currently employed population (persons who either worked or had a job at any time during the 2 weeks prior to the week of interview).

Following a pattern similar to that for days of restricted activity, the rate of work loss was lowest among white-collar workers and highest among farmers and farm laborers (fig. 2). However, the high rate of work loss among farm workers was due to the excessive rate of work loss among those aged 45 years and over. This rate was appreciably higher among nonwhite farmers and service workers than among white persons in these occupational categories.

Since rates of work loss may be influenced by whether actual loss of pay is involved, comparative data are shown in table E for the occupational categories according to class of worker. Tabulated information was not available for the entire period July 1961-June 1963, so the data shown in table E pertain only to the interval July 1961-June 1962. However, the general pattern of work loss was probably quite similar for the two periods. When currently employed persons of all ages were considered, the rate of work loss was highest

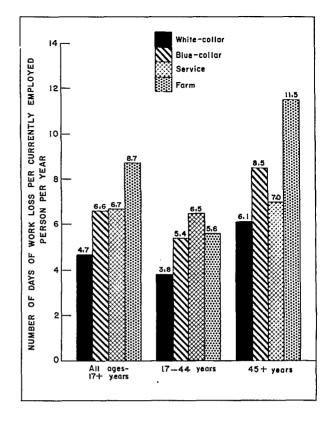

Figure 2. Number of days of work loss per currently employed person per year, by occupational category and age.

among self-employed persons and among those working for the Federal Government. Because of the sick-leave privileges granted to Federal workers and the flexibility of work schedules for self-employed persons, absenteeism was less likely to involve actual loss of income in these two classes than in other classes of workers. The large proportion of farmers in the self-employed group accounted for the high rate of work loss among the self-employed, since farmers had a higher rate of absenteeism than any of the other occupational categories (fig. 2). Among Federal employees. the rate of work loss was highest among bluecollar and service workers, while the high rate of work loss among the self-employed was attributable to blue-collar and farm workers.

Table E. Average number of days of work loss per currently employed person per year, by class of worker, age, and occupational category: United States, July 1961-June 1962

Among currently employed persons 17-44 years of age the rates of work loss were actually lower among Federal employees and selfemployed persons than among those working for privately owned organizations or for local governments. Even so, absenteeism due to illness was appreciably higher among Federal employees classified as service workers than for any of the other classes of service workers. It is apparent from the data shown in table E that the high rates of work loss among persons aged 45 years and over who were classified as Federal workers and as selfemployed persons were responsible for the excessive amounts of work loss for these two classes among currently employed persons of all ages.

ILLNESS AMONG PERSONS

IN THE LABOR FORCE

Even though illness and injury among persons in the labor force were important causes of absenteeism, the rate of acute and chronic ailments among working persons was much lower than in other segments of the population. The high incidence of childhood diseases and respiratory conditions among persons under 17 years of age and the increased prevalence of chronic conditions among persons aged 45 years and over, many of whom are forced to drop out of the labor force because of illness, have been responsible for the general characterization of the labor force (particularly the currently employed) as a comparatively healthy group of people.

Chronic Conditions

Estimates of chronic conditions based on health interviews include those the respondent is aware of, is willing to report to an interviewer, and can describe accurately enough to permit essentially reliable diagnostic classification. To encourage respondents to report conditions, many illness-recall questions are asked during the interview. As a result, all types of conditions are reported, ranging in severity from hay fever and sinusitis to heart conditions and cancer. Because of this broad spectrum of diseases, the measure "persons with one or more chronic conditions," which is used in the Survey to describe the extent of chronic illness in the population, loses much of its sensitivity. It can be seen from data shown in tables 18 and 19 that more than half of the persons in the labor force had one or more chronic conditions.

To provide a more meaningful measure of the effect of chronic illness on persons in the labor force, estimates of the persons with activity limitation resulting from chronic illness per 1,000 population are shown in these tables. Although the same data were presented on a percentage basis earlier in this report, they are repeated here to serve as a baseline on which to project the amount of disability due to heart conditions, arthritis and rheumatism, and orthopedic impairments—some of the leading causes of disability in the labor force.

Because of the magnitude of the sampling error, the estimates of disability due to these 3 condition categories are not reliable for some of the 12 occupational groups shown in the detailed tables. However, in table F estimates are summarized into the four major occupational categories. It is apparent from this table that farmers and farm laborers, regardless of age, had a higher rate of activity limitation than any other occupational group. Orthopedic impairment was the leading cause of activity limitation in all of the occupational groups, but it was particularly high among farm workers aged 45 years and over. Heart conditions and arthritis and rheumatism causing activity limitation were also more prevalent among farm workers aged 45 years and over than among other workers of the same age. Among whitecollar workers the rate of heart conditions causing activity limitation was consistently higher than for blue-collar workers.

The low rate of activity limitation among females as compared with that for males was probably due to the fact that females are more likely to drop out of the labor force when they become limited in their ability to work.

Acute Conditions

The 118.5 million acute conditions occurring during a year among persons in the labor force represented about 30 percent of the 401.3 million cases for the entire population. The rate per 1,000 persons in the labor force was 1,658.2 conditions per year (table 20), as compared with 1,753.0 among all persons 17+ years. For respiratory conditions, comparable rates were 949.7 per 1,000 in the labor force and 997.9 among all persons 17 years and over.

With the exception of those for laborers (both farm and other), the rates of acute conditions were higher among persons aged 17-44 years than among those aged 45 years and over in all occupational groups. In general, rates of acute conditions were higher among females than among males (table 21).

For the four occupational categories shown in figure 3, acute conditions occurred less frequently among blue-collar and farm workers than among white-collar and service workers. These rates reflect the pattern established for acute respiratory conditions, a category comprising more than 50 percent of the total acute conditions in each occupational group.

Persons Injured

Based on data collected during the 2-year period July 1961-June 1963, an annual estimate of 19 million persons in the labor force sustained injuries. This represented an annual rate of 266.4 persons injured per 1,000 population in the labor force, as compard with a rate of 242.9 per 1,000 in the general population 17 years and older.

13

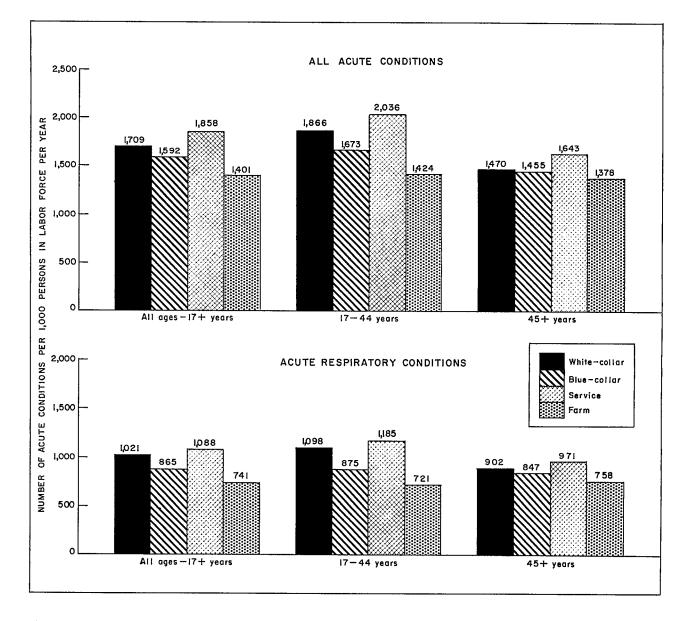

Figure 3. Incidence of acute conditions among persons in the labor force per year, by occupational category and age.

In tables 22-25, data on persons injured are shown according to the class of accident causing the injury. In some instances accidents may have been categorized in more than one class. For example, a person injured in a car accident while working at his job may have been appropriately classified as injured in a motor vehicle accident and also in an accident while at work. For this reason, the summation of the rates for the various classes of accidents shown in these tables exceeds the rate of persons injured.

Estimates shown in table 22 indicate that about 44 percent of the persons in the labor force sustaining injuries were injured while at work. Because the estimate of persons injured was based on injuries occurring during the 2-week period prior to interview and because the currently employed population was defined as persons working or having a job during that same period, a person injured while at work must, by definition, have been classified as currently employed. However, in order that comparability with other classes of accidents could be maintained, the rates for work injuries shown in tables G, 23, and 25 were based on persons in the labor force. These rates would have been slightly higher if they had been based on the currently employed population estimates shown in table 38.

The highest rates of work injury occurred among laborers (except farm or mine); craftsmen, foremen, and kindred workers; operatives and kindred workers; farmers; and farm laborers. Rates of injury in these occupational groups were higher among persons aged 17-44 years than among those aged 45 years and over.

Home accidents were highest among professional, technical, and kindred workers and among private household workers. Females, representing a comparatively large proportion of the persons in these two groups, were responsible for these high rates (table 24).

Injuries in moving and nonmoving motor vehicles occurred most frequently among blue-

15

collar workers (table G). The rates of work accidents were higher among males than among females in the labor force, while the rate of home accidents was markedly higher among females. Persons aged 17-44 years were injured more frequently than those aged 45 years and over. This difference by age was most pronounced among blue-collar workers and farmers (fig. 4).

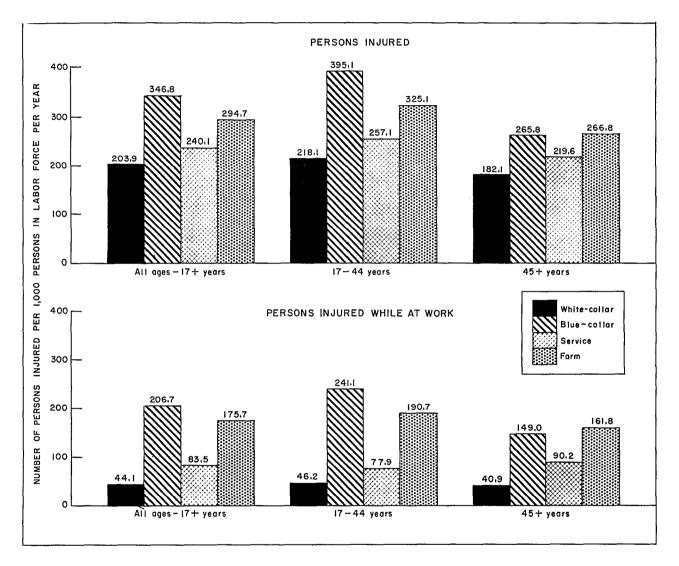

Figure 4. Number of persons injured and those injured while at work per 1,000 persons in the labor force per year, by occupational category and age.

MEDICAL SERVICES

In this report, data on the use of medical services are limited to the volume of hospital discharges, the number of hospital days, and the average length of stay per discharge for persons in the labor force and for those currently employed. Unfortunately, information on physician and dental visits was not collected during the 2-year period when occupation was an item on the interview questionnaire. However, two related topics, health insurance coverage and expenditures for medical and dental care, provide some information on the use of medical services among persons in the labor force.

Hospital Discharges and Hospital Days

As mentioned earlier, data collected in the Health Interview Survey refer only to persons who were alive at the time of the interview. For this reason, hospital data provide information on the hospital experience of the living population but do not assess the total amount of care provided by short-stay hospitals during a given year.

In the collection of data on hospitalization, information is obtained on all hospital stays during the year prior to interview. Validation studies on the completeness of reporting. in which information given in the interview was compared with hospital records, show that comparatively recent hospitalizations are easily recalled by the respondent. However, the accuracy with which hospital episodes are reported decreases as the interval between date of hospital discharge and date of interview increases. (See Vital and Health Statistics, Series 2, No. 6, p. 31.) For this reason, in the processing of the collected data only those hospital discharges which occurred during the most recent 6 months prior to interview were included in the estimates. By doubling the weights used in adjusting the sample data in order to represent the entire population, it was possible to obtain an estimate of the number of hospital discharges in an average year. Hospital days were adjusted in the same manner.

Approximately 6 million discharges, or 84.2 per 1,000 persons in the labor force, occurred during an average year (tables 26 and 27). This number represented about 27 percent of the discharges for the entire population during the same period. Hospital days for discharges during an average year amounted to approximately 52 million for persons in the labor force, representing about 32 percent of the days for the entire population. The average length of stay per discharge was 8.6 days, slightly longer than the average of 8.4 hospital days for the general population. The length of stay ranged from 7.0 days among clerical and kindred workers to 10.4 days among craftsmen, foremen, and kindred workers. The length of stay for this latter group may have been associated with the high rate of persons injured, particularly in work accidents.

For persons in the labor force who were aged 17-44 years, the rate of hospital discharge was lower and the length of stay was shorter than comparable measures for persons aged 45 years and over. However, among service workers the rate of discharge was higher for younger persons (table H).

The difference in the rates of hospital discharges for white persons (86.1 per 1,000 persons) and nonwhite persons (69.7 per 1,000) in the labor force was about the same as the difference by color in the general population. However, this color difference was not consistent in the various occupational groups (table 28). Among clerical and kindred workers and sales workers there was little difference in the rates of discharges for white and nonwhite persons; among private household workers, the rate of hospital discharge was higher for non-white than for white persons.

The average length of hospital stay was slightly shorter among white-collar workers than among persons in other occupational categories (fig. 5). Among persons in the labor force aged 45 years and over, hospital stay was shorter for white-collar and service workers than for blue-collar and farm workers.

Health Insurance Coverage

In this report, health insurance coverage is defined as any plan, group or individual, specifically designed to pay all or part of the medical expenses of the insured person. Excluded are plans limited to "dread diseases," free care given to veterans or given through health programs such as the Uniformed Services Dependents Medical Care Plan and the Crippled Children Program, insurance which pays bills only for accidents, and insurance which pays only for loss of income. A more precise definition of health insurance as considered in the Health Interview Survey can be found in Appendix II.

Data on two major forms of insurance coverage, hospital and surgical, are shown for the period July 1962-June 1963. Approximately 76.4 percent of the persons 17 years of age and over in the labor force had hospital insurance, and 71.0 percent had surgical insurance. Comparable rates for all persons aged 17 years and over not in the labor force were 63 percent with hospital insurance coverage and 57 percent with surgical insurance. While the rates of coverage among persons aged 17 years and over in the labor force were significantly higher than those for persons not in the labor force, the difference was far less than that existing between rates for employed and unemployed persons in the labor force. Comparative data on insurance coverage for employed and unemployed persons are shown by age and for occupational categories in an earlier report, Series 10, No. 11, tables 15 and 16. It should be noted that estimates for the category "farmers and farm managers" shown in table 16 also included data for craftsmen, foremen, and kindred workers. Through an oversight in the preparation of the table, the occupational category was inaccurately described.

Among the occupational groups the highest rates of hospital insurance were for professional, technical, and kindred workers (87.2 percent) and for clerical and kindred workers (86.7 percent). For both males and females in these two groups the rate of hospital insurance coverage was over 85 percent and the surgical insurance was in excess of 80 percent (tables 29 and 30).

Particularly low rates of health insurance were noted for farmers, farm laborers, and private household workers. These low coverage rates were probably due to the irregular work patterns of many members of these groups as well as to their lack of opportunity to obtain insurance through organized employee groups.

In the four major occupational categories, the white-collar workers had hospital insurance coverage approximating 85 percent (fig. 6); there was very little difference in the rate of coverage for males (84.2 percent) and for

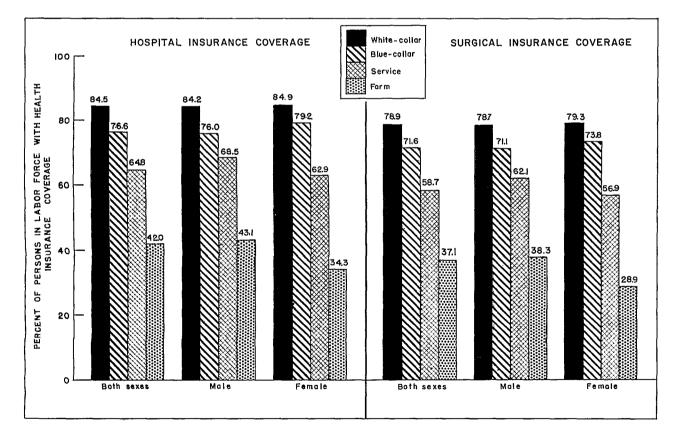

Figure 6. Percent of persons in the labor force with hospital and surgical insurance, by occupational category and sex.

females (84.9 percent). About 77 percent of the blue-collar workers had hospital insurance coverage, with the rate for females (79.2) exceeding that for males (76.0 percent).

The lower rate of coverage among female service workers in comparison with the rate for males in this occupational category was due to the high proportion of females classified as private household workers, a group with a very low rate of health insurance coverage (table 30). The coverage rate for farm workers (42.0 percent) was heavily weighted by the high proportion of males in this category. In all of the occupational categories the pattern of surgical insurance coverage was quite similar to that for hospital insurance, although in each category the coverage level was 5 or 6 percentage points lower for surgical insurance.

From data shown in table J it is apparent that insurance coverage among white- and bluecollar workers followed a typical pattern when considered by age. This pattern consisted of a comparatively low rate of coverage among those 17-24 years of age, peak rates for the age groups 25-44 and 45-64 years, and a decrease in coverage for those 65 years and over to a level equivalent to that for persons aged 17-24 years. For service and farm workers, however, the peak rates of coverage among those 25-64 years of age were sustained among those aged 65 years and over who were still in the labor force. The reduction in coverage among white- and blue-collar workers aged 65 years and over may have been related to the fact that many persons retired from these occupational groups at age 65. Persons who remain in the labor force beyond age 65 years probably consist of a heterogeneous group. Many stay in the working population because they have insufficient retirement benefits and therefore would be less likely to have insurance coverage. On the other hand, service and farm workers, particularly private household workers and farm owners, tend to remain in the working population beyond 65 years of age; thus, their insurance coverage rates would not be essentially different from those for persons aged 45-64 years in these occupational categories (tables 31 and 32).

Occupational category	A11 ages	17-24 years	25-44 years	45 - 64 years	65 1 years

Table J. Percent of persons aged 17+ years in the labor force with health insurance, by age and occupational category: United States, July 1962-June 1963

Personal Health Expenses

Data on the amount of money persons spend for health care during an average year were collected in the Health Interview Survey during July-December 1962. Even though the collection of information was limited to a time span of 6 months, the period to which the questions on expenditures referred was the 12 months prior to interview. Therefore, annual estimates largely free from seasonal bias could be derived from the responses to these questions.

The material on health expenses was collected by self-enumeration. On completion of the routine health questionnaire, the interviewer gave the respondent forms designed to obtain information for each member of the family about the types and amounts of his health expenses during the year prior to interview. These forms, which on completion were submitted by mail, became a part of the person's interview record. This procedure encouraged respondents to refer to medical bills and other records so that the data submitted would be more complete and accurate.

Households for which forms were not returned or for which certain items of data were missing were contacted by telephone to obtain the needed information. Despite this followup procedure, nonresponse was about 6 percent. Because of the unstated expenditures, the estimates of health costs presented in this report were based on known data. This procedure was based on the assumption that medical expenses for the entire labor force (or currently employed) were distributed in the same proportion as expenses for members of the labor force who responded in the sample population.

Health-expense data shown in this report represent the value of services received or products purchased by persons in the labor force and include expenses paid for by health insurance. Excluded are the costs of health insurance premiums as well as services or items paid for either by Federal, State, or local agencies or by welfare or other freecare programs. Also excluded are expenses of families of military personnel if the expenses were covered by medicare.

Based on data collected in the Survey, the average person 17 years of age and over in the labor force spent approximately \$142 per year for medical and dental care. In comparison, the average expenditure for the total population (persons of any age) was \$129. and for persons 17 years and over. \$164. There was very little difference in health expenses per person in the labor force and per currently employed person (tables 33-36); however, since the labor force data were heavily weighted by the estimates for currently employed persons, this similarity does not mean that there was little or no difference in health expenses for currently employed and for unemployed persons.

The types of expenses that were noticeably higher in the labor force than in the general population were doctor and dental expenses. The higher amounts in these two types of health expenses were attributable for the most part to the relatively large expenditures of white-collar workers. For all of the age groups shown in table K dental expenses were markedly higher among white-collar workers than among persons in other occupational categories; in all age groups 25 years and over, doctor expenses followed this same pattern. The unusually high doctor and hospital expenses among service workers aged 17-24 years were due to expenses reported by private household workers. Undoubtedly some part of these expenses were associated with prenatal and postnatal care and hospitalization for delivery.

All types of health expenses for farm workers were significantly lower than for any of the other occupational categories. Although all kinds of medical expenses increased with advancing age in each of the four major occupational categories, the differentials in successive age groups among farm workers were less than the differences by age in the other occupational groups.

The average amount of health expense per person for those aged 65 years and over in the labor force was \$195. Persons of the same age group in the general population spent an average of \$208 per person for health purposes. The types of expenses that contributed to this difference were hospital costs, which averaged \$53 for the total population aged 65 years and over and \$48 for persons in the same age group in the labor force, and expenses for medicine, which amounted to \$54

per person per year in the general population and \$42 for those in the labor force who were 65 years of age or over.

DETAILED TABLES

CHRONIC LIMITATION STATUS

Table	1.	Number of persons aged 17+ years in the labor force, by chronic limitation sta- tus, age, and occupation: United States, July 1961-June 1963 26
	2.	Percent distribution of persons aged 17+ years in the labor force, by chronic limitation status according to age and occupation: United States, July 1961-June 1963 27
	3.	Number of persons aged 17+ years in the labor force with 1+ chronic conditions, and the proportion currently employed, by chronic limitation status, age, and occupation: United States, July 1961-June 1963 28
	4.	Number of persons aged 17+ years in the labor force, by chronic limitation sta- tus, sex, and occupation: United States, July 1961-June 1963 29
	5.	Percent distribution of persons aged 17+ years in the labor force, by chronic limitation status according to sex and occupation: United States, July 1961-June 1963 30
	6.	Number of persons aged 17+ years in the labor force, by chronic limitation sta- tus, color, and occupation: United States, July 1961-June 1963 31
	7.	Percent distribution of persons aged 17+ years in the labor force, by chronic limitation status according to color and occupation: United States, July 1961- June 1963 32
	8.	Number of persons aged 17+ years in the labor force, by chronic limitation sta- tus, family income, and occupation: United States, July 1961-June 1963 33
	9.	Percent distribution of persons aged 17+ years in the labor force, by chronic limitation status according to family income and occupation: United States, July 1961-June 1963
	10.	Number of persons aged 17+ years in the labor force, by chronic limitation sta- tus, education of individual, and occupation: United States, July 1961-June 1963- 35
	11.	Percent distribution of persons aged 17+ years in the labor force, by chronic limitation status according to education of individual and occupation: United States, July 1961-June 1963 36
		DAYS OF DISABILITY
	12.	Average annual number of days of disability for persons aged 17+ years in the labor force and for the currently employed, by age and occupation: United States, July 1961-June 1963 37

13. Average number of days of disability per person per year for persons aged 17+ years in the labor force and for the currently employed, by age and occupation: United States, July 1961-June 1963------ 38

:

14. Average annual number of days of disability for persons aged 17+ years in the labor force and for the currently employed, by sex and occupation: United States, July 1961-June 1963------ 39

Page

DAYS OF DISABILITY-Con.

- Table 15. Average number of days of disability per person per year for persons aged 17+ years in the labor force and for the currently employed, by sex and occupation: United States, July 1961-June 1963-----40
 - Average annual number of days of disability for persons aged 17+ years in the labor force and for the currently employed, by color and occupation: United States, July 1961-June 1963-----16. 41
 - 17. Average number of days of disability per person per year for persons aged 17+ years in the labor force and for the currently employed, by color and occupa-tion: United States, July 1961-June 1963-----42

CHRONIC ILLNESS AND ACTIVITY LIMITATION

- 18. Extent of chronic illness and activity limitation in the labor force, and se-lected conditions causing limitation, by sex and occupation: United States, July 1961-June 1963------43
- 19. Extent of chronic illness and activity limitation in the labor force, and se-lected conditions causing limitation per 1,000 persons in the labor force, by sex and occupation: United States, July 1961-June 1963------44

ACUTE CONDITIONS

- 20. Average annual incidence of acute conditions and acute respiratory conditions among persons aged 17+ years in the labor force, conditions per 1,000 persons in the labor force, and percent medically attended, by age and occupation: United States, July 1961-June 1963-----45
- 21. Average annual incidence of acute conditions and acute respiratory conditions among persons aged 17+ years in the labor force, conditions per 1,000 persons in the labor force, and percent medically attended, by sex and occupation: United States, July 1961-June 1963------46

PERSONS INJURED

22.	Average annual number of persons injured (aged 17+ years) in the labor force, by class of accident, age, and occupation: United States, July 1961-June 1963	47
23.	Average annual number of persons injured (aged 17+ years) per 1,000 persons in the labor force, by class of accident, age, and occupation: United States, July 1961-June 1963	48
24.	Average annual number of persons injured (aged 17+ years) in the labor force, by class of accident, sex, and occupation: United States, July 1961-June 1963	49
25.	Average annual number of persons injured (aged 17+ years) per 1,000 persons in the labor force, by class of accident, sex, and occupation: United States, July 1961-June 1963	50
	HOSPITAL DISCHARGES AND HOSPITAL DAYS	
26.	Average annual number of hospital discharges and hospital days for persons aged 17+ years in the labor force and for the currently employed, by age and occupa- tion: United States, July 1961-June 1963	51
27.	Average annual number of hospital discharges and hospital days for persons aged 17+ years in the labor force and for the currently employed, by sex and occupa- tion: United States, July 1961-June 1963	52

28. Average annual number of hospital discharges and hospital days for persons aged 17+ years in the labor force and for the currently employed, by color and occupation: United States, July 1961-June 1963------53

APPENDIX I

TECHNICAL NOTES ON METHODS

Background of This Report

This report is one of a series of statistical reports prepared by the National Health Survey. It is based on information collected in a continuing nationwide sample of households in the Health Interview Survey, a major part of the program.

The Health Interview Survey utilizes a questionnaire which, in addition to personal and demographic characteristics, obtains information on illnesses, injuries, chronic conditions and impairments, and other health topics. As data relating to each of these various broad topics are tabulated and analyzed, separate reports are issued which cover one or more of the specific topics. The present report is based on the consolidated sample for 104 weeks of interviewing ending June 1963.

The population covered by the sample for the Health Interview Survey is the civilian, noninstitutional population of the United States living at the time of the interview. The sample does not include members of the Armed Forces, U.S. nationals living in foreign countries, or crews of vessels. It should also be noted that the estimates shown do not represent a complete inventory of injuries for the specified calendar period since no adjustment has been made for persons who incurred injuries during the 2-week-recall period but who died prior to the interview.

Statistical Design of the Health Interview Survey

General plan.—The sampling plan of the survey follows a multistage probability design which permits a continuous sampling of the civilian population of the United States. The first stage of this design consists of drawing a sample of 357 from about 1,900 geographically defined primary sampling units (PSU's) into which the United States has been divided. A PSU is a county, a group of contiguous counties, or a standard metropolitan statistical area.

With no loss in general understanding, the remaining stages can be combined and treated in this discussion as an ultimate stage. Within PSU's, then, ultimate stage units called segments are defined in such a manner that each segment contains an expected nine households. A segment consists of a cluster of neighboring households or addresses. Two general types of segments are used: (1) area segments which are defined geographically, and (2) B segments which are defined from a list of addresses from the Decennial Census and Survey of Construction. Each week a random sample of about 90 segments is drawn. In the approximately 800 households in these segments, household members are interviewed concerning factors related to health.

Since the household members interviewed each week are a representative sample of the population, samples for successive weeks can be combined into larger samples. Thus the design permits both continuous measurement of characteristics of high incidence or prevalence in the population and, through the larger consolidated samples, more detailed analysis of less common characteristics and smaller categories. The continuous collection has administrative and operational advantages as well as technical assets, since it permits field work to be handled with an experienced, stable staff.

Sample size and geographic detail.—Over the 2year period ending June 1963 the sample included about 259,000 persons from 80,000 households in about 11,100 segments.

The overall sample was designed in such a fashion that tabulations can be provided for each of the major geographic regions and for urban and rural sectors of the United States.

Collection of data.—Field operations for the household survey are performed by the Bureau of the Census under specifications established by the National Center for Health Statistics. In accordance with these specifications the Bureau of the Census selects the sample, conducts the field interviewing as an agent of the Center, and performs a manual editing and coding of the questionnaires. The Health Survey, using Center electronic computers, carries out further editing and tabulates the edited data.

Estimating methods.—Each statistic produced by the survey—for example, the number of persons with one or more chronic conditions, in a specified period—is the result of two stages of ratio estimation. In the first of these, the control factor is the ratio of the 1960 decennial population count to the 1960 estimated population in the National Health Survey's first-stage sample of PSU's. These factors are applied for some 25 colorresidence classes.

Later, ratios of sample-produced estimates of the population to official Bureau of the Census figures for

current population in about 60 age-sex-color classes are computed, and serve as second-stage factors for ratio estimating.

The effect of the ratio-estimating process is to make the sample more closely representative of the population by age, sex, color, and residence, thus reducing sampling variance.

As noted, each week's sample represents the population living during that week and characteristics of this population. Consolidation of samples over a time period, say a calendar quarter, produces estimates of average characteristics of the U.S. population for that calendar quarter. Similarly, population data for a year are averages of the four quarterly figures.

For statistics measuring the number of occurrences during a specified time period, such as the number of bed-disability days, a similar computational procedure is used, but the statistics are interpreted differently. For these items, the questionnaire asks for the respondent's experience over the 2 calendar weeks prior to the week of interview. In such instances the estimated quarterly total for the statistic is simply 6.5 times the average 2-week estimate produced by the 13 successive samples taken during the period. The annual total is the sum of the four quarters. Thus, the experience of persons interviewed during a year-experience which actually occurred for each person in a 2-calendar-week interval prior to week of interview-is treated as though it measured the total of such experience during the year. Such interpretation leads to no significant bias.

General Qualifications

Nonresponse.—Data were adjusted for nonresponse by a procedure which imputes to persons in a household which was not interviewed the characteristics of persons in households in the same segment which were interviewed. The total noninterview rate was 5 percent; l percent was refusal, and the remainder was primarily due to the failure to find any eligible household respondent after repeated trials.

The interview process.—The statistics presented in this report are based on replies secured in interviews of persons in the sampled households. Each person 19 years of age and over, available at the time of interview, was interviewed individually. Proxy respondents within the household were employed for children and for adults not available at the time of the interview, provided the respondent was closely related to the person about whom information was being obtained.

There are limitations to the accuracy of diagnostic and other information collected in household interviews. For diagnostic information, the household respondent can, at best, pass on to the interviewer only the information the physician has given the family. For conditions not medically attended, diagnostic information is often no more than a description of symptoms. However, other facts, such as the number of disability days caused by the condition, can be obtained more accurately from household members than from any other source since only the persons concerned are in a position to report this information.

Rounding of numbers. — The original tabulations on which the data in this report are based show all estimates to the nearest whole unit. All consolidations were made from the original tabulations using the estimates to the nearest unit. In the final published tables the figures are rounded to the nearest thousand, although these are not necessarily accurate to that detail. Devised statistics, such as rates and percent distributions, are computed after the estimates on which these are based have been rounded to the nearest thousand.

Population figures. -- Some of the published tables include population figures for specified categories. Except for certain overall totals by age and sex, which are adjusted to independent estimates, these figures are based on the sample of households in the National Health Survey. These are given primarily to provide denominators for rate computation and for this purpose are more appropriate for use with the accompanying measures of health characteristics than other population data that may be available. In some instances these will permit users to recombine published data into classes more suitable to their specific needs. With the exception of the overall totals by age and sex, mentioned above, the population figures differ from corresponding figures (which are derived from different sources) published in reports of the Bureau of the Census. For population data for general use, see the official estimates presented in Bureau of the Census reports in the P-20, P-25, and P-60 series.

Reliability of Estimates

Since the estimates are based on a sample, they will differ somewhat from the figures that would have been obtained if a complete census had been taken using the same schedules, instructions, and interviewing personnel and procedures. As in any survey, the results are also subject to measurement error.

The standard error is primarily a measure of sampling variability, that is, the variations that might occur by chance because only a sample of the population is surveyed. As calculated for this report, the standard error also reflects part of the variation which arises in the measurement process. It does not include estimates of any biases which might lie in the data. The chances are about 68 out of 100 that an estimate from the sample would differ from a complete census by less than the standard error. The chances are about 95 out of 100 that the difference would be less than twice the standard error and about 99 out of 100 that it would be less than 2½ times as large.

The relative standard error of an estimate is obtained by dividing the standard error of the estimate by the estimate itself and is expressed as a percentage of the estimate. Included in this Appendix are charts from which the relative standard errors can be determined for estimates shown in the report. In order to derive relative errors which would be applicable to a wide variety of health statistics and which could be prepared at a moderate cost, a number of approximations were required. As a result, the charts provide an estimate of the approximate relative standard error rather than the precise error for any specific aggregate or percentage.

Three classes of statistics for the health survey are identified for purposes of estimating variances.

Narrow range.—This class consists of (1) statistics which estimate a population attribute, e.g., the number of persons in a particular income group, and (2) statistics for which the measure for a single individual for the period of reference is usually either 0 or 1, on occasion may take on the value 2, and very rarely, 3.

Medium range. — This class consists of other statistics for which the measure for a single individual for the period of reference will rarely lie outside the range 0 to 5.

Wide range. — This class consists of statistics for which the measure for a single individual for the period of reference frequently will range from 0 to a number in excess of 5, e.g., the number of days of bed disability experienced during the year.

In addition to classifying variables according to whether they are narrow-, medium-, or wide-range, statistics in the survey are further defined as:

- Type A.—Statistics on prevalence and incidence data for which the period of reference in the questionnaire is 12 months.
- Type B.—Incidence-type statistics for which the period of reference in the questionnaire is 2 weeks.

Only the charts on sampling error applicable to data contained in this report are presented.

General rules for determining relative sampling errors.—The "guide" on page 67, together with the following rules, will enable the reader to determine approximate relative standard errors from the charts for estimates presented in this report.

- Rule 1. Estimates of aggregates: Approximate relative standard errors for estimates of aggregates, such as the number of persons with a given characteristic, are obtained from appropriate curves on pages 68, 70, and 73. The number of persons in the total U.S. population or in an age-sex class of the total population is adjusted to official Bureau of the Census figures and is not subject to sampling error.
- Rule 2. Estimates of percentages in a percent distribution: Relative standard errors for

percentages in a percent distribution of a total are obtained from appropriate curves on pages 69, 71, and 72. For values which do not fall on one of the curves presented in the chart, visual interpolation will provide a satisfactory approximation.

- Rule 3. Estimates of rates where the numerator is a subclass of the denominator: This rule applies for prevalence rates or where a unit of the numerator occurs, with few exceptions, only once in the year for any one unit in the denominator. For example, in computing the rate of orthopedic impairments per 1,000 population, the numerator consisting of persons with the impairment is a subclass of the denominator which includes all persons in the population. Such rates if converted to rates per 100 may be treated as though they were percentages, and the relative standard errors obtained from the chart, P8AN-M. Rates per 1,000, or on any other base, must first be converted to rates per 100; then the percentage chart will provide the relative standard error per 100.
- Rule 4. Estimates of rates where the numerator is not a subclass of the denominator: This rule applies where a unit of the numerator often occurs more than once for any one unit in the denominator. For example, in the computation of the number of persons injured per 1,000 currently employed persons per year, it is possible that a person in the denominator could have sustained more than one of the injuries included in the numerator. Approximate relative standard errors for rates of this kind may be computed as follows:
 - (a) Where the denominator is the total U.S. population, or includes all persons in one or more of the age-sex groups of the total population, the relative error of the rate is equivalent to the relative error of the numerator which can be obtained directly from the appropriate chart.

,

(b) In other cases, obtain the relative standard error of the numerator and of the denominator from the appropriate curve. Square each of these relative errors, add the resulting values, and extract the square root of the sum. This procedure will result in an upper bound and often will overstate the error.

Guide to Use of Relative Standard Error Charts

The code shown below identifies the appropriate curve to be used in estimating the relative standard error of the statistic described. The four components of each code describe the statistic as follows: (1) A=

.....

. .

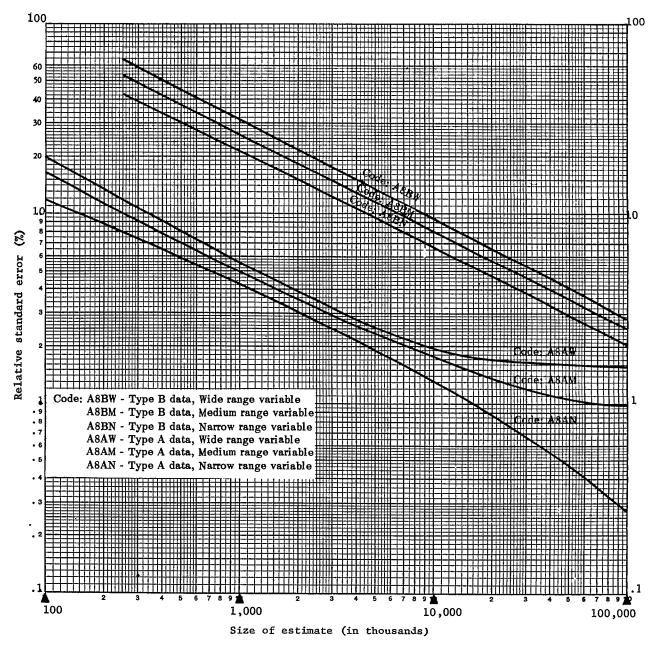

ł

aggregate, P=percentage; (2) the number of calendar quarters of data collection; (3) the type of the statistic as described on page 66; and (4) the range of the statistic as described on page 66.

67

Example of use of chart: An aggregate of 5,000,000 (on scale at bottom of chart) for a Narrow range type A statistic (code: A8AN) has a relative standard error of 1.9 percent, read from scale at left side of chart, or a standard error of 95,000 (1.9 percent of 5,000,000). For a Wide range type B statistic (code: A8BW), an aggregate of 10,000,000 has a relative error of 9.3 percent or a standard error of 930,000 (9.3 percent of 10,000,000).

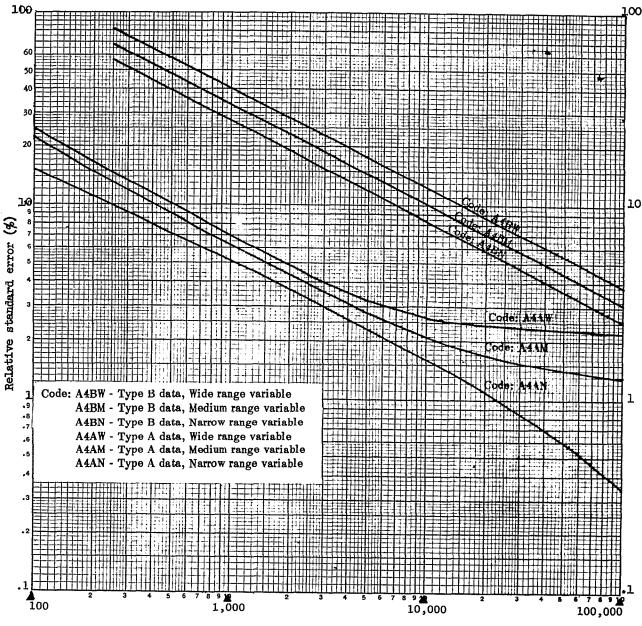

(Base of percentage shown on curves in millions)

Estimated percentage

T

Example of use of chart: An estimate of 20 percent (on scale at bottom of chart) based on an estimate of 10,000,000 has a relative standard error of 2.8 percent (read from the scale at the left side of the chart), the point at which the curve for a base of 10,000,000 intersects the vertical line for 20 percent. The standard error in percentage points is equal to 20 percent X 2.8 percent or 0.56 percentage points.

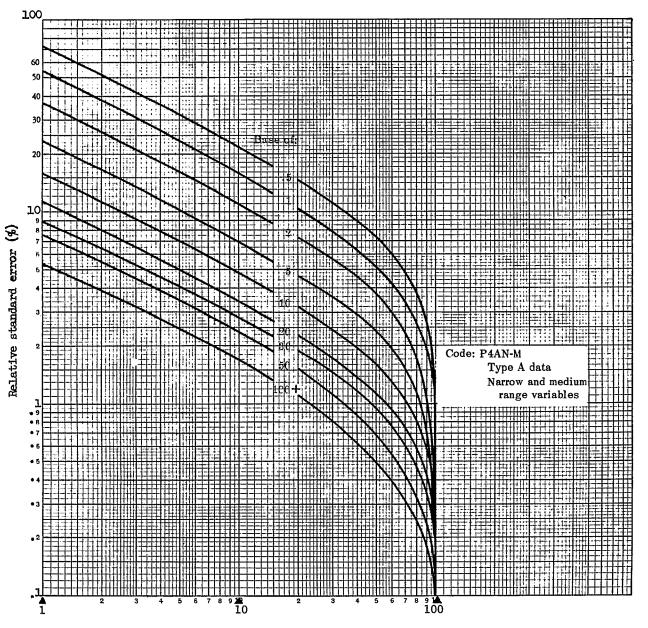

Size of estimate (in thousands)

Example of use of chart: An aggregate of 2,000,000 (on scale at bottom of chart) for a Narrow range Type A statistic (code: A4AN) has a relative standard error of 3.6 percent, (read from scale at left side of chart), or a standard error of 72,000 (3.6 percent of 2,000,000). For a Wide range Type B statistic (code: A4BW), an aggregate of 6,000,000 has a relative error of 16.0 percent or a standard error of 960,000 (16 percent of 6,000,000).

Relative standard errors for percentages based on four quarters of data collection for type A data, Narrow and Medium range (Poso of percentage sharp on survey in millions)

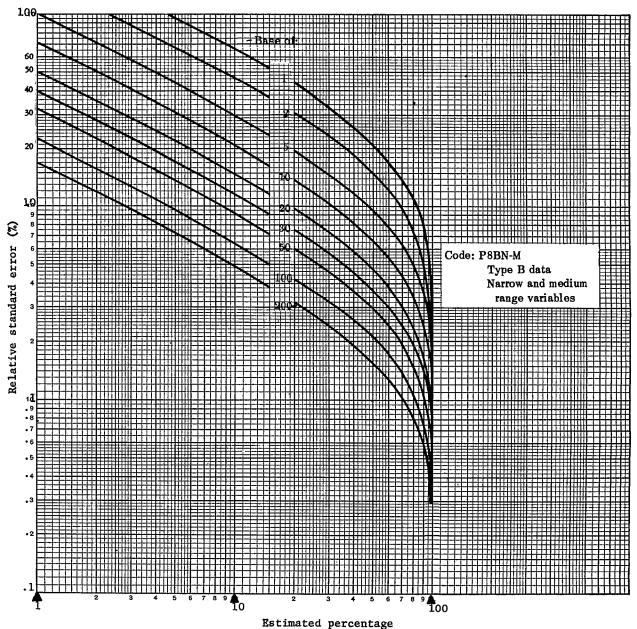

(Base of percentage shown on curves in millions)

Estimated percentage

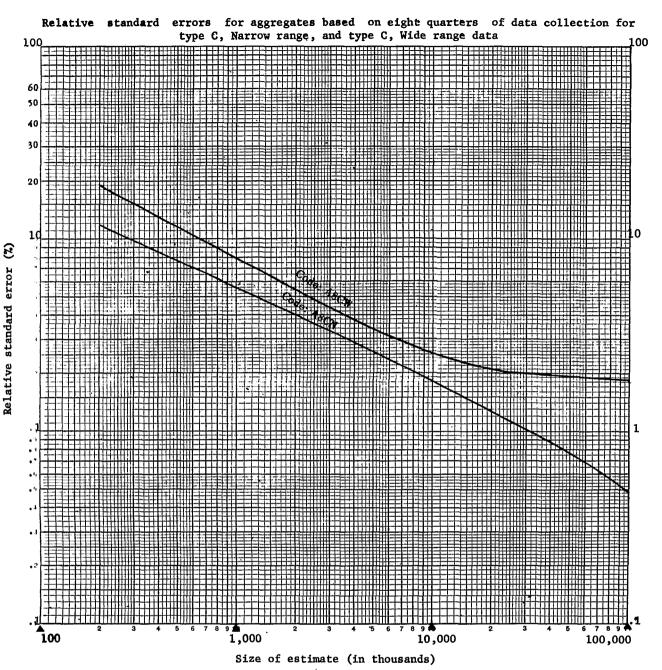

Example of use of chart: An estimate of 20 percent (on scale at bottom of chart) based on an estimate of 10,000,000 has a relative standard error of 3.2 percent (read from the scale at the left side of the chart), the point at which the curve for a base of 10,000,000 intersects the vertical line for 20 percent. The standard error in percentage points is equal to 20 percent X 3.2 percent or 0.64 percentage points.

Relative standard errors for percentages based on eight quarters of data collection for type B data, Narrow and Medium range (Base of percentage shown on curves in millions)

Example of use of chart: An estimate of 20 percent (on scale at bottom of chart) based on an estimate of 10,000,000 has a relative standard error of 13.8 percent (read from scale at the left side of the chart), the point at which the curve for a base of 10,000,000 intersects the vertical line for 20 percent. The standard error in percentage points is equal to 20 percent X 13.8 percent or 2.8 percentage points.

1

Example of use of chart: An aggregate of 1,000,000 (on scale at bottom of chart) for a Narrow range type C statistic (code: A8CN) has a relative standard error of 5.6 percent, read from scale at left side of chart, or a standard error of 56,000 (5.6 percent of 1,000,000).

ì

APPENDIX II

DEFINITIONS OF CERTAIN TERMS USED IN THIS REPORT

Terms Relating to Employment

In the labor force.—This includes all persons 17 years of age and older who worked at or had a job or business or were looking for work, or on layoff from work during the 2-week period prior to week of interview. The labor force consists of persons currently employed and those unemployed, as defined below.

Currently employed— This includes persons 17 years of age or over who reported that at any time during the 2-week period covered by the interview they either worked at, or had a job or business. Current employment includes paid work as an employee of someone else, self-employment in business, farming, or professional practice, and unpaid work in a family business or farm. Persons who were temporarily absent from their job or business because of a temporary illness, vacation, strike, or bad weather are considered as currently employed if they expected to work as soon as the particular event causing their absence no longer existed.

Free-lance workers are considered as currently employed if they had a definite arrangement with one or more employers to work for pay according to a weekly or monthly schedule, either full time or part time. Excluded from the currently employed are such persons who have no definite employment schedule but work only when their services are needed.

Also excluded from the currently employed population are (1) persons receiving revenue from an enterprise in whose operation they do not participate, (2) persons doing housework or charity work for which they receive no pay, and (3) seasonal workers during the portion of the year they were not working.

Currently unemployed— This includes persons 17 years and over who during the 2-week period prior to interview, did not work, had no job or business, but were looking for work; or persons with a job but on layoff or looking for work.

Persons not in labor force.— Persons not in the labor force are all persons under 17 years of age, and other persons who did not, at any time during the 2week period covered by the interview, have a job or business, were not looking for work, and were not on layoff from a job. In general, persons excluded from the labor force are: children under 17, retired persons, the physically handicapped unable to work, and housewives or charity workers who receive no pay. Occupation. — A person's occupation may be defined as his principal job or business. For the purposes of this Survey, the principal job or business is defined in one of the following ways. If the person worked during the 2-week-reference period of the interview, or had a job or business, the question concerning his occupation (or what kind of work he was doing), applies to his job during that period. If the respondent held more than one job, the question is directed to the one at which he spent the most time. For an unemployed person, this question refers to the last full-time civilian job he had. A person who has a job to which he has not yet reported, and has never had a previous job or business, is classified as a "new worker."

Terms Relating to Chronic Conditions

Condition.—A morbidity condition, or simply a condition, is any entry on the questionnaire which describes a departure from a state of physical or mental well-being. It results from a positive response to one of a series of "illness-recall" questions. In the coding and tabulating process, conditions are selected or classified according to a number of different criteria, such as, whether they were medically attended; whether they resulted in disability; whether they were acute or chronic; or according to the type of disease, injury, impairment, or symptom reported. For the purposes of each published report or set of tables, only those conditions recorded on the questionnaire which satisfy certain stated criteria are included.

Conditions, except impairments, are coded by type according to the International Classification of Diseases with certain modifications adopted to make the code more suitable for a household-interview-type survey.

Chronic condition.— A condition is considered to be chronic if (1) it is described by the respondent in terms of one of the chronic diseases on the "Check List of Chronic Conditions" or in terms of one of the types of impairments on the "Check List of Impairments" or (2) the condition is described by the respondent as having been first noticed more than 3 months before the week of the interview.

Impairments.—Impairments are chronic or permanent defects, resulting from disease, injury, or congenital malformation. They represent decrease or loss of ability to perform various functions, particularly those of the musculoskeletal system and the sense organs. All impairments are classified by means of a special supplementary code for impairments. Hence, code numbers for impairments in the International Classification of Diseases are not used. In the Supplementary Code, impairments are grouped according to type of functional impairment and etiology.

Persons with chronic conditions.—The estimated number of persons with chronic conditions is based on the number of persons who at the time of the interview were reported to have one or more chronic conditions.

Prevalence of conditions.— In general, prevalence of conditions is the estimated number of conditions of a specified type existing at a specified time or the average number existing during a specified interval of time. The prevalence of chronic conditions is defined as the number of chronic cases reported to be present or assumed to be present at the time of the interview; those assumed to be present at the time of the interview are cases described by the respondent in terms of one of the chronic diseases on the "Check List of Chronic Conditions" and reported to have been present at some time during the 12-month period prior to the interview.

Terms Relating to Disability

Chronic activity limitation.—Persons with chronic conditions are classified into four categories according to the extent to which their activities are limited at present as a result of these conditions. Since the usual activities of preschool children, school-age children, housewives, and workers and other persons differ, a different set of criteria is used for each group. There is a general similarity between them, however, as will be seen in the descriptions of the four categories below:

 Persons unable to carry on major activity for their group (major activity refers to ability to work, keep house, or go to school) Preschool children: inability to take part in

	2 <u>1</u>
	ordinary play with other
	children.
School-age children:	inability to go to school.
Housewives:	inability to do any house- work.
Workers and all	
other persons:	inability to work at a job or business.

2. Persons limited in the amount or kina of major activity performed (major activity refers to ability to work, keep house, or go to school) Preschool children: limited in the amount or kind of play with other children, e.g., need special rest periods, cannot play strenuous games, cannot play for long periods at a time.

	School-age children: Housewives:	limited to certain types of schools or in school at- tendance, e.g., need spe- cial schools or special teaching, cannot go to school full time or for long periods at a time. limited in amount or kind
		of housework, i.e., cannot liftchildren, wash or iron, or do housework for long periods at a time.
	Workers and all	
•	other persons:	limited in amount or kind of work, e.g., need spe- cial working aids or spe- cial rest periods at work, cannot work full time or for long periods at a time, cannot do strenuous work.
3.	Persons not limited in	ımajor activity but other-
••	wise limited (major activity refers to ability to	
	work, keep house, or go to school)	
	Preschool children:	not classified in this cate-
	Tresensor emiliren.	gory.
	School-age children:	not limited in going to school but limited in par- ticipation in athletics or other extracurricular ac- tivities.
	Housewives:	not limited in housework but limited in other ac- tivities, such as church, clubs, hobbies, civic proj- ects, or shopping.
	Workers and all	,
	other persons:	not limited in regular work activities but limited
		in other activities, such as church, clubs, hobbies, civic projects, sports, or
4	Persons not limited i	games.
ч.	- croons not timiled t	n ucholles

 Persons not limited in activities Includes persons with chronic conditions whose activities are not limited in any of the ways described above.

Terms Relating to Disability Days

Disability.—Disability is the general term used to describe any temporary or long-term reduction of a person's activity as a result of an illness or injury.

Disability days are classified according to whether they are days of restricted activity, bed-days, or workloss days. All days of bed disability are, by definition, days of restricted activity. The converse form of this statement is, of course, not true. Days lost from work are also days of restricted activity for the working populations. Hence, restricted activity is the most inclusive term used in describing disability days.

Condition-days of restricted activity, bed disability, etc.—Condition-days of restricted activity, bed disability, and so forth are days of the various forms of disability associated with any one condition. Since any particular day of disability may be associated with more than one condition, the sum of days for conditions may add to more than the total number of person-days.

Restricted-activity day.—A day of restricted activity is one on which a person substantially reduces the amount of activity normal for that day because of a specific illness or injury. The type of reduction varies with the age and occupation of the individual as well as with the day of the week or season of the year. Restricted activity covers the range from substantial reduction to complete inactivity for the entire day.

Bed-disability day.—A day of bed disability is one on which a person stays in bed for all or most of the day because of a specific illness or injury. All or most of the day is defined as more than half of the daylight hours. All hospital days for inpatients are considered to be days of bed disability even if the patient was not actually in bed at the hospital.

Work-loss day.—A day lost from work is a normal working day on which a person did not work at his job or business because of a specific illness or injury. If the person's regular work day is less than a whole day and the entire work day was lost, it would be counted as a whole work day lost. The number of days lost from work is determined only for persons 17 years of age or over who reported that at any time during the 2-week period covered by the interview they either worked at or had a job or business. (See "Currently employed persons.")

Person-days of restricted activity, bed disability, etc.—Person-days of restricted activity, bed disability, and so forth are days of the various forms of disability experienced by any one person. The sum of days for all persons in a group represents an unduplicated count of all days of disability for the group.

Terms Relating to Acute Conditions

Acute condition.—An acute condition is defined as a condition which has lasted less than 3 months and which has involved either medical attention or restricted activity. Because of the procedures used to estimate incidence, the acute conditions included in this report are the conditions which had their onset during the 2 weeks prior to the interview week and which involved either medical attention or restricted activity during that 2week period. However, certain conditions which are always classified as chronic regardless of onset have been excluded.

Onset of condition.—A condition is considered to have had its onset when it was first noticed. This could be the time the person first felt sick or became injured,

or it could be the time when the person or his family was first told by a physician that he had a condition of which he was previously unaware.

Incidence of conditions.—The incidence of conditions is the estimated number of conditions having their onset in a specified time period. As previously mentioned, minor acute conditions involving neither restricted activity nor medical attention are excluded from the statistics. The incidence data shown in some reports are further limited to various subclasses of conditions, such as "incidence of conditions involving bed disability."

Activity-restricting condition.—An activity-restricting condition is any condition which has caused at least 1 day of restricted activity during the 2 calendar weeks before the interview week. (See definition of "Restricted-activity day.") The incidence of acute activity-restricting conditions is estimated from the number of such conditions reported as having started in the 2-week period.

Bed-disabling condition.—A condition involving at least 1 day of bed disability during the 2 calendar weeks before the interview week is called a bed-disabling condition. (See definition of "Bed-disability day.") The incidence of acute bed-disabling conditions is defined in a manner analogous to the incidence of acute activity-restricting conditions.

Medically attended condition.—A condition is considered medically attended if a physician has been consulted about it either at its onset or at any time thereafter. Medical attention includes consultation either in person or by telephone for treatment or advice. Advice from the physician transmitted to the patient through the nurse is counted as well as visits to physicians in clinics or hospitals. If during the course of a single visit the physician is consulted about more than one condition for each of several patients, each condition of each patient is counted as medically attended.

Discussions of a child's condition by the physician and a responsible member of the household are considered as medical attention even if the child was not seen at that time.

For the purpose of this definition, the term "physician" includes doctors of medicine and osteopathic physicians.

Terms Relating to Persons Injured

Injury condition.—An injury condition, or simply an injury, is a condition of the type that is classified to the nature of injury code numbers (N800-N999) in the International Classification of Diseases. In addition to fractures, lacerations, contusions, burns, and so forth, which are commonly thought of as injuries, this group of codes includes the effects of exposure, such as sunburn; adverse reactions to immunizations and other medical procedures; and poisonings. Unless otherwise specified, the term injury is used to cover all of these. Since a person may sustain more than one injury in a single accident, e.g., a broken leg and laceration of the scalp, the number of injury conditions may exceed the number of persons injured.

Statistics of current or acute injury conditions include only injuries which involved at least 1 full day of restricted activity or medical attendance.

Person injured.—A person injured is one who has sustained an injury in an accident, or in some type of nonaccidental violence. (See definition of "Injury condition," above). Each time a person is injured he is included in the statistics as a separate "person injured"; hence, one person may be included more than once.

The statistics of persons injured include only persons sustaining injuries which involved at least one full day of restricted activity or medical attendance.

The number of persons injured is not equivalent to the number of "accidents" for several reasons: (1) the term "accident," as commonly used, may not involve injury at all; (2) more than one injured person may be involved in a single accident so that the number of accidents resulting in injury would be less than the number of persons injured in accidents; and (3) the term "accident" ordinarily implies an accidental orgin, whereas "persons injured," as used in the National Health Survey, includes persons whose injury resulted from certain nonaccidental violence.

The number of persons injured in a specified time interval is always equal to or less than the incidence of injury conditions, since one person may incur more than one injury in a single accident.

Class of accident.—This is a broad classification of the types of events which resulted in persons being injured. Most of these events are accidents in the usual sense of the word; but some are other kinds of mishap. such as overexposure to the sun or adverse reactions to medical procedures, and others are nonaccidental violence, such as attempted suicide. The classes of accidents are (1) motor vehicle accidents, moving and nonmoving, (2) accidents occurring while at work, (3) home accidents, and (4) other accidents. These categories are not mutually exclusive. For example, a person may be injured in a motor-vehicle accident which occurred while he was at work. In this report, accidents which could be assigned to more than one class have been so classified. Therefore, the summation of events by class of accident will exceed the total number of persons injured.

Motor-vehicle accident.— The class of accident is "motor vehicle" if a motor vehicle was involved in any way. Thus, it is not restricted to moving motor vehicles or to persons riding in motor vehicles. A motor vehicle is any mechanically or electrically powered device, not operated on rails, upon which or by which any person or property may be transported or drawn upon a land highway. Any object, such as a trailer, coaster, sled, or wagon, being towed by a motor vehicle is considered a part of the motor vehicle. Devices used solely for moving persons or materials within the confines of a building and its premises are not counted as motor vehicles.

Moving motor vehicle.—The accident is classified as "moving motor vehicle" if at least one of the motor vehicles involved in the accident was moving at the time of the accident. The vehicle was moving if the wheels were in motion at the time of the accident.

Nonmoving motor vehicle.—The accident is classified as "nonmoving motor vehicle" if the motor vehicle was not moving at the time of the accident.

Accident while at work.—The class of accident is "while at work" if the injured person was 17 years of age or over and was at work at a job or a business at the time the accident happened.

Home accident.—The class of accident is "home" if the injury occurred either inside the house or outside the house. "Outside the house" refers to the yard, buildings, and sidewalks on the property. "Home" includes not only the person's own home but also any other home in which the injury might have occurred.

Other.—The class of accident is "other" if the occurrence of injury cannot be classified in one or more of the first three class-of-accident categories. This category therefore includes persons injured in public places (e.g., tripping and falling in a store or on a public sidewalk), and also nonaccidental injuries such as homicidal and suicidal attempts. The survey does not cover the military population, but current disability of various types resulting from prior injury occurring while the person was in the Armed Forces is covered and is included in this class. The class also includes mishaps for which the class of accident could not be ascertained.

Terms Relating to Hospitalization

Hospital discharge.—A hospital discharge is the completion of any continuous period of stay of 1 or more nights in a hospital, as an inpatient, except the period of stay of a well, newborn infant. A hospital discharge is recorded whenever a present member of the household is reported to have been discharged from a hospital in the 12-month period prior to the interview week. For certain reports of the National Health Survey, estimates were based on discharges which occurred during the 6-month period prior to the interview.

Hospital.—A hospital is defined as any institution meeting one of the following criteria: (1) named in the listing of hospitals in the current Guide Issues of Hospitals, the Journal of the American Hospital Association; (2) named in the listing of hospitals in the Directories of the American Osteopathic Hospital Association; or (3) named in the annual inventory of hospitals and related facilities submitted by the States to the Division of Hospital and Medical Facilities of the Public Health Service in conjunction with the Hill-Burton program. Short-stay hospital.— A short-stay hospital is one for which the type of service is general; maternity; eye, ear, nose, and throat; children's; osteopathic hospital; or hospital department of institution.

Hospital day.—A hospital day is a day on which a person is confined to a hospital. The day is counted as a hospital day only if the patient stays overnight. Thus, a patient who enters the hospital on Monday afternoon and leaves Wednesday noon is considered to have had 2 hospital days.

Estimates of the total number of hospital days are derived by summing the days for all hospital discharges. (See definition of "Hospital discharge.")

Length of hospital stay.—The length of hospital stay is the duration in days, exclusive of the day of discharge, of a hospital discharge. (See definition of "Hospital discharge.")

Average length of hospital stay.—The average length of hospital stay per discharged patient is computed by dividing the total number of hospital days for a specified group by the total number of discharges for the same group.

Health Insurance Terms

Health insurance is any plan specifically designed to pay all or part of the medical or hospital expenses of each insured individual in the household. The insurance can be either a group or an individual policy with the premiums paid by the individual, his employer, a third party, or a combination of these. Benefits received under the plan can be in the form of payment to the individual or to the hospital or doctor. However, the plan must be a formal one with defined membership and benefits rather than an informal one. For example, an employer simply paying the hospital bill for an employee would not constitute a health insurance plan.

For the National Health Survey, health insurance excludes the following kinds of plans: (1) plans limited to the "dread diseases," such as cancer and polio; (2) free care such as public assistance or public welfare, care given free of charge to veterans, care given to dependents of military personnel (Medicare), care given under the Crippled Children or similar programs, and care of persons admitted for research purposes; (3) insurance which pays bills only for accidents, such as liability insurance held by a car or property owner, insurance that covers children for accidents at school or camp, and insurance for a worker that covers him only for accidents on the job; and (4) insurance which pays only for loss of income.

Hospital insurance coverage.—Hospital insurance coverage is insurance which pays all or part of the hospital bill for the hospitalized person. By hospital bill is meant only the bill submitted by the hospital itself, not the doctor's or surgeon's bill or the bill for special nurses. Such a bill always includes the cost of room and meals and may also include the costs of other services such as operating room, laboratory tests, X-rays, etc.

Surgical insurance coverage.— Surgical insurance coverage is insurance which pays in whole or part the bill of the doctor or surgeon for an operation whether performed in a hospital or in the doctor's office. Insurance which pays the cost of visits to a doctor's office for postoperative care is included as surgical insurance.

Terms Relating to Costs of Medical and Dental Care

Costs of medical and dental care.—These are the total expenditures for medical and dental care for a person during a specified 12-month period. The National Health Survey collects the data for each member of a household in the Survey sample for the specified 12month period. The total expenditures are defined as all bills paid (or to be paid) for medical and dental care by the person himself, his family or friends, and any part paid by health insurance. This is included whether it is paid directly to the hospital or doctor, or paid to the person himself, or to his family. If a respondent does not know the exact amount paid by insurance, he is requested to estimate it and include it in the total bill.

For the National Health Survey, expenditures for medical and dental care exclude amounts paid (or to be paid) by workmen's compensation, nonprofit organizations, military services including Medicare, Veterans Administration, and Federal, State, city, or county governments.

If a baby is born in the household during the specified 12-month period, the hospital and doctor bills relating to the baby's birth are included in medical expenditures for the mother. However, all other medical expenditures relating to the baby's health are counted in the medical expenditures for the baby.

There are six categories of personal health expenditures for medical and dental care as follows:

- 1. Doctors' bills.—Doctors' bills are defined as the total bills paid (or to be paid) for medical care to doctors, including surgeons, for a person during the specified 12-month period. Such bills include costs of operations, treatments, checkups, deliveries, pregnancy care, X-rays, laboratory fees, eye examinations, immunizations or shots, and any other doctors' services provided for the patient.
- 2. Hospital bills.—Hospital bills are the total expenditures paid (or to be paid) for hospitalizations of a person during the specified 12-month period. Only hospitalizations for overnight or longer in a hospital (nursing home, rest home, sanitarium, etc.) are counted. Hospital bills include costs of room and board,

operating and delivery room, anesthesia, special treatments, X-rays, tests, and any other hospital services provided and billed for by the hospital.

- 3. *Medicine costs.*—Medicine costs are total expenditures paid (or to be paid) for medicine for a person during the specified 12-month period. The total expenditures for medicine include the costs of all kinds of medicine whether or not prescribed by a doctor, such as tonics, pills, prescriptions, salves, ointments, vitamins, and any other medicine. But health foods, soaps, cosmetics, and similar preparations are excluded.
- 4. Dentists' bills.—Dentists' bills are defined as the total bills paid (or to be paid) for dental care for a person during the specified 12-month period. Dentists' bills include costs of fillings, extractions, cleanings, X-rays, bridgework, dental plates, straightening of teeth, and any other dental services.
- 5. Special medical expenses.—Special medical expenses paid (or to be paid) for a person during the specified 12-month period include costs of the following: eye glasses, hearing aids, special nursing, physical therapy, speech therapy, corrective shoes, chiropractors' fees, and special braces or trusses, wheel chairs, or artificial limbs.
- 6. Other medical expenses.—All medical expenses for a person during the specified 12-month period not included above are classified as other. For example, emergency or outpatient treatment in a hospital or clinic would be classified as other.

Demographic, Social, and Economic Terms

Age.—The age recorded for each person is the age at last birthday. Age is recorded in single years and grouped in a variety of distributions depending upon the purpose of the table.

Color.—In this report, the population has been subdivided into two groups according to color, "White" and "Nonwhite." "Nonwhite" includes Negro, American Indian, Chinese, Japanese, and so forth. Mexican persons are included with "White" unless definitely known to be Indian or another nonwhite race.

Family income.—Each member of a family is classified according to the total income of the family of which he is a member. Within the household all persons related to each other by blood, marriage, or adoption constitute a family. Unrelated individuals are classified according to their own income.

The income recorded is the total of all income received by members of the family in the 12-month period prior to the week of interview. Income from all sources is included, e.g., wages, salaries, rents from property, pensions, help from relatives, and so forth.

Education.—Each person age 17 or older is classified by education in terms of the highest grade of school completed. Only grades completed in regular schools, where persons are given a formal education, are included. A "regular" school is one which advances a person toward an elementary or high school diploma, or a college, university, or professional school degree. Thus, education in vocational, trade, or business schools outside the regular school system is not counted in determining the highest grade of school completed.

SELECTED REPORTS FROM THE NATIONAL CENTER FOR HEALTH STATISTICS Public Health Service Publication No. 1000

Series 1. Programs and collection procedures

- No. 1. Origin, Program, and Operation of the U.S. National Health Survey. 35 cents.
- No. 2. Health Survey Procedure: Concepts, Questionnaire Development, and Definitions in the Health Interview Survey. 45 cents.
- No. 3. Development and Maintenance of a National Inventory of Hospitals and Institutions. 25 cents.
