#### COOPERATION OF THE BUREAU OF THE CENSUS

Under the legislation establishing the National Health Survey, the Public Health Service os authorized to use, insofar as possible, the services or facilities of other Federal, State, or private agencies.

In accordance with specifications established by the Health Interview Survey, the Bureau of the Census, under a contractual arrangement, participates in most aspects of survey planning, selects the sample, and collects the data.

# AGE PATTERNS IN MEDICAL CARE, ILLNESS, AND DISABILITY

Christy Namey and Ronald W. Wilson, Division of Health Interview Statistics

#### INTRODUCTION

The health care legislation of the mid-1960's was expected to bring about changes in the health status of the U.S. population, particularly among persons 65 years and over. An earlier report contained baseline information on the use of medical services, illness, and disability from the pre-Medicare period July 1963-June 1965.<sup>1</sup> The present report contains similar information from the post-Medicare period January 1968-December 1969. Data are presented on the frequency and duration of hospitalization, physician and dental visits, disability days due to illness, limitation of activity associated with chronic conditions and impairments, the frequency of accidental injuries, and health insurance coverage.

In order to facilitate comparison between the two time periods, the format of this report is similar to that of the earlier one. Several changes were necessary, however, as a result of modifications in the collection procedures. The data pertain to calendar years rather than fiscal years. Information on certain variables such as the number of persons with one or more chronic conditions is no longer collected in the survey; also several variables have been added. The earlier report used only one age group for persons under 45 years, while this one shows data for persons under 17 years and 17-44 years of age. The two age categories 65-74 years and 75 years and over are maintained where possible to give special emphasis to the aged. The highest income category was increased from \$10,000 and over to \$15,000 and

over to account for rising income levels. Although the earlier report presented some data by color, for the majority of the health characteristics in this publication color is shown by "white" and "all other."

Most of the information contained in this report is based on 1968-69 data. Where marked changes have occurred between pre-Medicare and post-Medicare periods, the affected areas are discussed.

The following statements summarize some of the data presented in this report:

#### 1968-69 Findings

White persons had a higher rate of hospital discharges but a shorter length of stay than did all other persons.

Lower income groups had a higher rate of hospitalization and longer lengths of stay.

Males had a lower rate of physician visits than females at all ages except for persons under 17 years.

About 69 percent of the population had had a physician visit during the year prior to the interview and only 45 percent had had a dental visit.

About two out of five persons 65 years and over reported some activity limitation caused by chronic conditions.

In general as persons advanced in age the number of injuries they incurred decreased. Approximately 60 percent of all injuries among persons 65 years and over occurred in the home.

#### Changes Between 1964 and 1969

Persons 65 years and over experienced a 25percent increase in the rate of discharges from short-stay hospitals between 1964 and 1969. There was also an increase in the average length of stay for older persons.

The rate of physician visits decreased between the 2 years, the largest change occurring among persons 65 years and over.

There was a 50-percent decrease in the proportion of physician visits to the home for persons 65 years and over.

Among those older persons there was a decrease of 4.1 days of restricted activity between 1964 and 1969.

#### DISTRIBUTION OF THE POPULATION

The population is classified in this report by those demographic characteristics which most clearly demonstrate the changes which take place as age progresses. Table A shows the population distribution by various age groups and table B by income categories. Only among persons under 17 years does the proportion of males exceed that of females. Men account for approximately 43 percent and women 57 percent of persons aged 65 years and over.

The proportion of persons other than white amounts to approximately 12 percent of the population. This percentage decreases with age while that of white persons increases (table A).

Over one-half of the civilian, noninstitutional population in the United States lives in families with income of \$7,000 or more (this estimate includes persons living alone). In comparison, about half of those 65 years and over live in families with income of less than \$4,000. Approximately two-thirds of persons other than white have family incomes of less than \$7,000 (table C).

The proportion of persons within each geographic region and within each area of residence is about the same for all age categories.

Only 6 percent of the total population lives alone; among persons 65 years and over, this proportion increases to 25 percent.

The most marked change in the distribution of the population between July 1963-June 1965 and 1968-69 was the change by family income. During

the earlier period 27.1 percent of all persons lived in families with incomes of less than \$4,000 and only 16.7 in families with incomes of \$10,000 or more. In the later period these proportions had changed to 17.6 and 31.9, respectively.

### SOURCE AND LIMITATIONS OF THE DATA

The information contained in this report is based on data collected in a continuous nationwide survey conducted by household interview. Each week a representative sample of households is interviewed to obtain information relating to the health characteristics of each member of the household.

The Health Interview Survey is limited to the civilian, noninstitutional population of the United States. For some kinds of information, such as the occurrence of injuries, the effect of this restriction on the data is negligible; for other types,

such as the impact of specific chronic conditions for which the rate of institutionalization is high. a considerable underestimation may result. Furthermore, the exclusion of institutionalized persons does not affect to any great extent the population estimates or the health data for persons under 65 years. However, among older persons, where the institutionalized population represents a much larger proportion of the total population. this restriction means that the health interview data do not completely describe the persons 65 years and over and that other sources on information must be used to supplement the interview material. For example, the records maintained in resident institutions are now being used in the Division of Health Resources Statistics to obtain sample data which will describe the health and care status of institutionalized persons.

Another general qualification of the survey is that the collected information refers only to persons who were alive at the time of the household interview. This exclusion of information for persons who died prior to the household interview tends to reduce certain types of estimates.

Since the estimates from the interview data are based on a sample, they will differ somewhat from figures that would have been obtained if a complete census had been taken using the same procedures. Most of the estimates are based on 2 years of data collection, 1968 and 1969. (This 2year period will be referred to in the text as 1969.) The estimates for physician visits and several other variables, however, are based on data collected during a single year.

A description of the design of the survey, the methods of estimation, and the general qualifications of survey data is presented in appendix I. As previously mentioned, the estimates shown in this report are based on a sample of the population and are therefore subject to sampling error. Although most of these errors are of relatively low magnitude, where an estimated number or the numerator or denominator of a rate or percentage is small, the sampling error may be high. For this reason, particular attention should be directed to the section in appendix I entitled "Reliability of Estimates." Charts of relative sampling errors and instructions for their use are also presented in appendix I.

Table D. Total short-stay hospital discharges, percent obtained from health interviews and from decedents, by sex and age: United States, July 1963-June 1964

Certain terms used in this report are defined in appendix II. Since many of the terms have specialized meanings for the purpose of the survey, the reader is advised to familiarize himself with these definitions.

The questionnaire used for the Health Interview Survey during 1969 and the insurance questions covered during 1968 are illustrated in appendix III.

#### USE OF MEDICAL SERVICES

Data are collected in the Health Interview Survey to measure quantitatively the medical care that the population receives. These measures include the rate of discharges from short-stay hospitals, average length of stay and percent of persons surgically treated, number of physician visits per person per year, and the proportion of the population who had physician and dental visits within the past year. In addition, data are presented on the place of physician visits.

Although material is presented for several age groups, this report emphasizes changes which have occurred in the use of medical services by the older population since the enactment of Medicare legislation. Data on hospitalizations are compared with baseline data collected by household interview during the period July 1963-June 1965. The earlier data on physician visits were collected during the 12-month period July 1963-June 1964. Both of these periods will hereinafter be referred to as 1964.

#### **Hospital Discharges**

The data from the Health Interview Survey pertain only to persons living in the household at the time of the interview, (Methods of estimation are shown in appendix I.) Because of this limitation, information on persons discharged from hospitals, on length of stay, and on surgical treatment is not included for persons who died prior to the interview date even though they were hospitalized during the reference period. The exclusion of data concerning these persons results in an underestimate of the hospital experience of older persons since both the rate of hospitalization and the mortality rate are higher for this group. A method of adjusting the data to include information on decedents is described in "Hospital Utilization in the Last Year of Life."<sup>2</sup> Estimates so adjusted have been published under the title "Hospital Discharges and Length of Stay: Short-Stay Hospitals, United States-July 1963-June 1964."<sup>3</sup> Table D shows that for the total number

of discharges during that period the experience of about 4.2 percent of persons hospitalized was not covered in interviews. According to the results of the National Mortality Survey, almost three-fifths (58.6 percent) of the discharges occurred among persons 65 years and over.

Annual discharges from short-stay hospitals for 1968-69 averaged 24,673,000. Persons aged 65 and over accounted for 4,302,000 of these; in other words, 9.4 percent of the population accounted for 17 percent of all hospital discharges.

The average length of stay per hospital discharge ranged from 5.6 days for persons under 17 years to 16.4 days for those 75 years and over. There was little difference between men and women aged 65 and over as to the average length of stay or the proportion treated surgically.

Table E. Rate of discharges from short-stay hospitals, by age and selected characteristics: United States, 1968-69

Persons other than white were hospitalized less frequently but they had longer average stays than white people. Discharges among persons 65 years and over amounted to 236.4 per 1,000 for white persons and 188.1 per 1,000 for all other persons. The average length of stay was 15.1 and 19.1 days, respectively.

Lower income groups generally had higher rates of hospitalization and longer lengths of stay.

For persons under 65 the length of stay decreased with few exceptions and the proportion undergoing surgery increased as income rose. For persons 65 years and over, however, there was little difference by income, about one out of three hospitalized persons having surgical treatment. Tables E and F summarize data on hospital discharges shown in tables 1-6.

Table F. Average length of stay in days for discharges from short-stay hospitals, by age and selected characteristics: United States, 1968-69

Between 1964 and 1969, the discharge rate for these older persons rose from 186.3 to 232.6 per 1,000 population, a 25-percent increase (figure 1). However, this increase should probably not be attributed entirely to the impact of Medicare since there was a corresponding 28-percent increase between 1959 and 1964. During the 5-year period the average length of stay for all persons 65 years and over rose from 12.7 to 15.3 days (figure 2).

There was very little change between 1964 and 1969 in the percentage of persons of all ages who had surgical treatment while hospitalized.

For age groups under 65 years the rate of hospital dishcarge was highest for nonfarm residents outside metropolitan area and lowest for farm residents. Table E shows that for persons over 65, however, farm residents had the highest discharge rate. Between 1964 and 1969 there was relatively little change by place of residence for persons under 65 but rather large increases in the discharge rate for those 65 years and over in

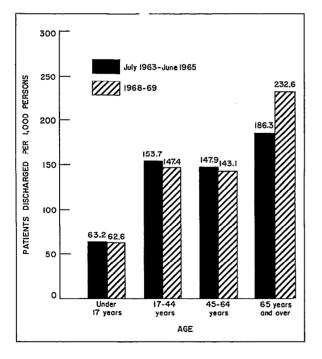

Figure 1. Rate of discharges from short-stay hospitals per 1,000 persons by age, July 1963-June 1965 and 1968-69.

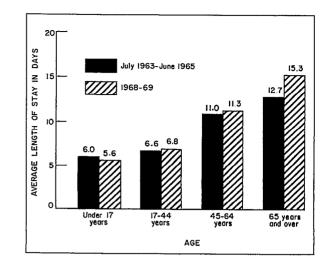

Figure 2. Average length of stay for short-stay hospitals by age, July 1963-June 1965 and 1968-69.

all areas, the largest being about 58 percent among farm residents (table G).

During the earlier period the average length of stay for all age groups decreased as the population became less concentrated. This was not the case in 1968-69. The more recent interview data indicate that the average length of stay for farm residents between 17 and 64 years more closely resembled that of metropolitan residents than that of nonfarm residents living in a nonmetropolitan area.

#### **Condition Causing Hospitalization**

Tables 7 and 8 show data on conditions for which persons were hospitalized. These estimates are based on data collected in household interviews in 1969 only. There were 25,517,000 hospitalizations; 36.2 percent were for deliveries, respiratory conditions, or injuries. These three conditions accounted for almost half the hospitalizations of persons under 45 years.

Among those 45-64 years, digestive system conditions and injuries ranked highest, approximately 17 and 11 percent. Heart and digestive system ailments caused one out of four hospitalizations among persons 65 years and over, a rate slightly less than that for 1964.

The average hospital stay for persons of all ages was longest for those with cerebrovascular

Table G. Hospital discharge rate and average length of stay for persons 65 years and over, by area of residence and selected years: United States

disease and mental and personality disorders and deficiencies. During 1963-65, the length of stay was longest for cerebrovascular disease and fractures and dislocations. The bias described previously for short-stay hospital discharges and length of stay affects especially the estimates for older persons by the condition for which they were hospitalized. The exclusion of data on persons who died prior to the interview date results in underestimates for conditions with a high fatality rate.

#### Physician Visits Per Person Per Year

Analysis of data collected in 1969 shows the usual pattern of an increase in physician visits as age progresses; from 3.6 visits per year for persons under 17 to 6.1 visits for those 65 years and over (tables H and 9). Males had a lower rate than females at all ages except for those under 17 years.

There was a decrease in the rate of physician visits between 1964 and 1969 (figure 3). For persons 65 years and over the 25-percent increase in hospitalization may account for some of the difference since physician visits to hospital inpatients are not counted except for data showing the interval since the last physician visit (appendix II and table 15). Increased use of nursing homes and sampling error may also contribute to the decreases between 1964 and 1969, when increases would ordinarily be expected due to Medicare provisions for persons aged 65 years and over.

Since the number of physicians in relation to the population increased between 1964 and 1969, the decrease in visits cannot be attributed to a drop in the ratio of physicians to the population.<sup>4</sup>

#### Physician Visits by Place of Visit

An estimated 70 percent of all physician visits in 1969 were made to doctor's offices; for persons 65 years and over, 74.4 percent were to the office and 8 percent were to the home.

Persons other than white had a higher percentage (22.5 percent) of visits to hospital clinics and emergency rooms than did white persons (8.9 percent). In addition, almost 14 percent of the visits of other than white children under 17 years of age occurred at some other place such as a school or a health department clinic compared to less than 5 percent of those of the white children (table 11). Additional data on place of visit by selected demographic variables can be found in tables 10-14.

Data in table J indicate that the increase between 1964 and 1969 in the proportion of office visits for the elderly was due primarily to a shift from home visits. In 1964, 17.3 percent of all visits for persons 65 years and over were made to the home compared to only 8.0 percent in 1969. The shift from home to office is even more dramatic when compared over a 10-year period, a drop from 22.8 percent in 1959 to 8.0

Table H. Number of physician visits per person per year, by age and selected characteristics: United States, 1969

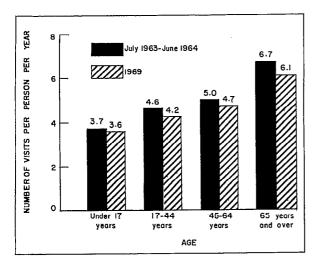

Figure 3. Number of physician visits per person per year by age, July 1963-June 1965 and 1968-69.

percent for these older persons and from 9.7 to 2.3 for the total population.

There was also an increase in proportion of visits in the "other and unknown" category although this increase was slight for the older population. Telephone consultations are listed in the detailed tables as a separate category of physician visit in this publication. The percentages for the category "other and unknown place of visits" for 1964 and 1969 are made comparable by adding the "telephone" and "other" categories for 1969.

#### Proportion of Persons With a Physician Visit Within a Year

About 69 percent of the total population received advice or treatment from a physician during the year prior to the interview. The proportion was higher for females (71.9 percent) than for males (66.7 percent) (table 15).

	Place of visit					
Age and date	Total	Home	Office	Hospital clinic	Other and unknown

Table J. Percent distribution of physician visits, by place of visit according to age and time period: United States

A higher proportion of white persons consulted a doctor during the year than did all other persons, particularly among those under 17 years (figure 4).

The percentage of persons with at least one visit during the year generally increased as family income rose, especially for children and to a lesser extent for persons 65 years and over. There was little difference by geographic region, but by area of residence a lower proportion of persons living in farm areas saw a physician during the year than did persons in more densely populated areas, particularly among those under 45 years.

A much lower percentage of never married persons 17 years and over received advice or treatment within the year than did married, divorced, separated, or widowed persons. Between the periods July 1963-June 1964 and January-December 1969 the proportion of persons of all ages who had a doctor visit within a year increased from 66.1 percent to 69.4 percent. For white persons the rate rose from 67.4 to 70.3 percent and for all other persons from 56.2 to 62.9 percent.<sup>5</sup>

#### Proportion of Persons With a Dental Visit Within a Year

Based on 1969 data, an estimated 45 percent of the population saw a dentist during the 12 months prior to the interview. The proportion decreased with advancing age, with slightly over one-half of the people 17-44 years seeing a dentist compared to less than a quarter of the older

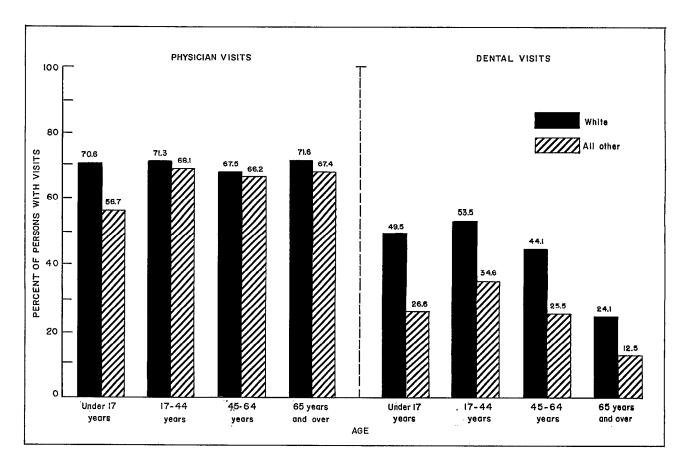

Figure 4. Percent of persons with physician visits and dental visits within a year by age and color, 1969.

population (table 16). As with physician visits, the percentage of the population with dental visits increased as family income rose. This is most noticeable for children—the percentage increasing from 24.5 for those in families with income under \$3,000 to 70.8 for those with family income of \$15,000 and over. The proportion of white persons with dental visits was 47 percent compared with 28 percent for persons other than white. The difference in utilization of medical services by color is more striking for dental than for physician visits, as shown in figure 4.

Between 1964 and 1969 the proportion of the population with a dental visit within a year rose from 42.0 to 45.0 percent with females having a higher percentage of visits than males during both years. The proportion of white persons who had a dental visit was twice as high as that for all other persons in 1964,<sup>6</sup> but the difference had decreased somewhat by 1969.

#### DISABILITY AND ILLNESS

In discussing Health Interview Survey data, several measures of disability are used to describe how disease, injury, and impairments affect peoples' ordinary activities. These measures are defined in appendix II.

Estimates based on data collected during 1968-69 indicate that the total population averaged 15 days of restricted activity per person per year (table K). Included in these 15 days were 6 days of bed disability (table 17). The average number of work-loss days among those currently employed was 5.3 days per year. Women in each age group above 17 years had more restricted activity and bed-disability days than did men. Tables 17-22 show additional detail on bed days and work-loss days.

Except for children under 17 years, white persons had lower rates than all other persons for all types of disability days. These differences increased with age. At age 65 years and over, the days of restricted activity averaged 33.1 for white persons and 47.6 for all other persons; bed disability, 13.1 and 20.5; and work-loss days, 5.4 and 10.1 days, respectively.

The rates of disability days of all kinds decreased as family income increased. Persons

with family income of less than \$3,000 experienced approximately 29 days of restricted activity, 11 days of bed disability. and 7 days of work-loss. Persons living in families with \$15,000 or more averaged 11, 5, and 4 disability days, respectively. In addition, this and previous studies show that the rate of disability days rises with age.<sup>7,8</sup> The higher rates among persons with the lowest incomes is explained partly by the fact that about 31.5 percent of those with family income of less than \$3,000 are 65 years and over while only 3.9 percent of those in families of \$15,000 and over are of this age; however, even within the age specific categories persons in low income families have the highest rate of restricted-activity davs.

Between 1964 and 1969 the number of restricted-activity days per person per year decreased from 16.3 to 15.0 days. For persons 65 years and over there was a drop of 4.1 days, 3.4 for men and 4.7 for women. Among this older group, the South had the largest change of all the regions, a decrease of about 10 restrictedactivity days per person. By area of residence, there was also a 14-day decrease for farm residents.

#### LIMITATION OF ACTIVITY DUE TO CHRONIC CONDITIONS

An estimated 22 million persons, or 11.2 percent of the population, reported they were limited in their activities as a result of a chronic condition (tables 23-28). Approximately 2.8 percent of the population were unable to carry on their major activities (working, keeping house, going to school, or participating in preschool activities); 6.3 percent were limited in the amount or kind of major activities such as civic and recreational endeavors.

About two out of every five persons 65 years and over had some activity limitation caused by chronic conditions. Over half of these were limited in the amount or kind of work or housework they could do, and about 16 percent of this older group were unable to carry on their major activities. A lower proportion of white persons 65 years and over had limitations than did other persons of the same age. The conditions of persons other than white led to more serious consequences—a larger proportion were unable to work or keep house.

There is an inverse relationship between family income and limitation of activity due to chronic conditions.<sup>9,10</sup> Table 25 supports this finding. For each age group shown in table L

activity limitation is higher among the low income groups. These people may not be aware of their conditions until they have disadvantageous effects on their daily lives. Persons in high income groups, on the other hand, make more use of medical care; consequently early diagnosis may lead to treatment before activity limitation occurs.

The data on limitation of activity are not directly comparable with the data for 1964 because information on all chronic conditions is no longer collected in the Health Interview Survey. The interested reader can approximate the 1969 "no limitation" category by adding the columns "persons with no chronic conditions" and "persons with one or more chronic conditions with no limitation of activity" for 1964.

Between 1964 and 1969 among persons 65 years and over there were decreases for both men and women in the proportion with limitation not connected with major activity and with some limitation in amount or kind of major activity.

However, for men there was an increase in the percentage who were unable to carry on their major activities.

By income the same pattern held for persons of all ages for both time periods, a decrease in limitation as income rose. For persons 65 years and over the change as income increased was not as great as that for younger persons in the two categories which caused limitation in major activities.

#### PERSONS INJURED

The term "persons injured" is limited in the Health Interview Survey to persons whose injuries

Table M. Rate of persons injured annually per 1,000 population, by age and selected characteristics: United States, 1968-69

either required medical attention or caused a reduction in usual activities for at least 1 day; minor injuries not meeting these criteria are excluded. Several of the estimates may be affected by these limitations. Persons with low family income, for example, are less able to afford medical attention or loss of work than are those of higher economic status.

Tables 29-34 show the number and rate of persons injured by class of accident and selected characteristics. A summary of these rates for all injuries is shown in table M.

In general, as persons advanced in age injuries decreased, with males having higher rates than females until the age of 65. Approximately 60 percent of the injuries among persons 65 years and over occurred in the home compared to about 31 percent for persons 17-64 years of age. The rates of home injuries are compared with "other" injuries in figure 5.

White persons, in general, reported more injuries than all other persons. This difference may be affected by the medical-attendance and restricted-activity criteria mentioned earlier because approximately two-thirds of the persons other than white live in families with income of less than \$7,000 while only one-third of the white persons fall in this income category. This possible undercount of injuries among persons other than white seems to be supported by the fact that these persons had injury rates comparable to white persons for accidents at work, where medical attention for any injury is usually provided.

Between 1964 and 1969 the number of persons injured per 1,000 population decreased from 287 to 249, a decrease of 35 per 1,000 for males and about 40 per 1,000 for females. Most of the change was due to fewer home accidents. Among males 65 years and over the decrease amounted to almost 41 per 1,000 persons.

The largest change by geographic region was for the North Central Region with a decrease of 58 per 1,000 persons. Home accidents accounted for a large proportion of this decrease.

#### HOSPITAL INSURANCE COVERAGE

Health insurance coverage, while not a direct measure of health status, is a theoretical indication of ability to pay for and avail oneself

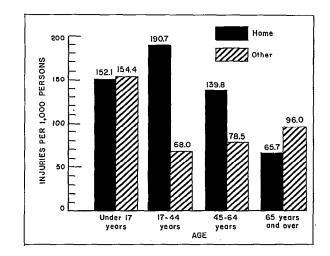

Figure 5. Rate of persons injured per 1,000 persons by age and class of accident, 1968-69.

of medical services. Data were collected on hospital and surgical insurance coverage during 1968. In that year nearly all persons 65 years of age and over were covered by the hospital benefits of Medicare; thus data are presented here only for persons under 65 years. In addition, the data shown in this report are restricted to hospital coverage since surgical coverage levels are only about 2 percentage points below hospital coverage.

Approximately 78.2 percent of the population under 65 years of age are covered by hospital insurance (table N). There is a slight increase as age increases, with 75.0 percent coverage for persons under 17 and 81.1-percent coverage for persons 45-64 years. These differences by age are more marked among persons other than white and among persons with family incomes under \$5,000. The greatest differences in hospital insurance coverage are by family income with 36.3percent coverage among persons with income under \$3,000 and 93.0-percent coverage among persons with incomes in excess of \$15,000. Although comparable insurance data are not available for the period of July 1963-June 1965, data from the July 1962-June 1963 Health Interview Survey indicate that 71.9 percent of the population under 65 years were covered by hospital insurance.<sup>11</sup>

#### LIST OF DETAILED TABLES

Table	S	Page
1.	Average number of discharges from short-stay hospitals, rate per 1,000 persons, number of hospital days, average length of hospital stay for discharges, and number and per- cent of persons surgically treated, by age and sex: United States, 1968-69	22
2.	Average number of discharges from short-stay hospitals, rate per 1,000 persons, num- ber of hospital days, average length of hospital stay for discharges, and number and percent of persons surgically treated, by age and color: United States, 1968-69	23
3.	Average number of discharges from short-stay hospitals, rate per 1,000 persons, number of hospital days, average length of hospital stay for discharges, and number and per- cent of persons surgically treated, by age and family income: United States, 1968-69	24
4.	Average number of discharges from short-stay hospitals, rate per 1,000 persons, number of hospital days, average length of hospital stay for discharges, and number and per- cent of persons surgically treated, by age and geographic region: United States, 1968-69	25
5.	Average number of discharges from short-stay hospitals, rate per 1,000 persons, number of hospital days, average length of hospital stay for discharges, and number and per- cent of persons surgically treated, by age and area of residence: United States, 1968-69	26
6.	Average number of discharges from short-stay hospitals, rate per 1,000 persons, number of hospital days, average length of hospital stay for discharges, and number and per- cent of persons surgically treated, by age and living arrangements: United States, 1968-69	27
7.	Number and percent distribution of discharges from short-stay hospitals by condition for which hospitalized, according to age: United States, 1969	28
8.	Number of hospital days and average length of stay in short-stay hospitals for dis- charges, by age and condition for which hospitalized: United States, 1969	29
9.	Number of physician visits and number of visits per person per year, by age and se- lected characteristics: United States, 1969	30
10.	Number and percent distribution of physician visits by place of visit, according to age and sex: United States, 1969	31
11.	Number and percent distribution of physician visits by place of visit, according to age and color: United States, 1969	32
12.	Number and percent distribution of physician visits by place of visit, according to age and family income: United States, 1969	33
13.	Number and percent distribution of physician visits by place of visit, according to age and geographic region: United States, 1969	34
14.	Number and percent distribution of physician visits by place of visit, according to age and area of residence: United States, 1969	35
15.	Number and percent of the population with one or more physician visits within a year, by age and selected characteristics: United States, 1969	36

.

#### Detailed Tables-Con.

Table	S	Page
16.	Number and percent of the population with or more dental visits within a year, by age and selected characteristics: United States, 1969	37
17.	Average number of disability days and number of disability days per person per year, by age and sex: United States, 1968-69	38
18.	Average number of disability days and number of disability days per person per year, by age and color: United States, 1968-69	39
19.	Average number of disability days and number of disability days per person per year, by age and family income: United States, 1968-69	40
20.	Average number of disability days and number of disability days per person per year, by age and geographic region: United States, 1968-69	41
21.	Average number of disability days and number of disability days per person per year, by age and area of residence: United States, 1968-69	42
22.	Average number of disability days and number of disability days per person per year, by age and living arrangements: United States, 1968-69	43
23.	Average number and percent discribution of persons by degree of limitation of activity due to chronic conditions, according to age and sex: United States, 1968-69	44
24.	Average number and percent distribution of persons by degree of limitation of activity due to chronic conditions, according to age and color: United States, 1968-69	45
25.	Average number and percent distribution of persons by degree of limitation of activity due to chronic conditions, according to age and family income: United States, 1968-69	46
26.	Average number and percent distribution of persons by degree of limitation of activity due to chronic conditions, according to age and geographic region: United States, 1968-69	47
27.	Average number and percent distribution of persons by degree of limitation of activity due to chronic conditions, according to age and area of residence: United States, 1968-69	48
28.	Average number and percent distribution of persons by degree of limitation of activity due to chronic conditions, according to age and living arrangements: United States, 1968-69	49
29.	Average number and rate of persons injured, by class of accident, age, and sex: United States, 1968-69	50
30.	Average number and rate of persons injured, by class of accident, age, and color: United States, 1968-69	51
31.	Average number and rate of persons injured, by class of accident, age, and family in- come: United States, 1968-69	52
32.	Average number and rate of persons injured, by class of accident, age, and geographic region: United States, 1968-69	53
33.	Average number and rate of persons injured, by class of accident, age, and area of residence: United States, 1968-69	54
34.	Average number and rate of persons injured, by class of accident, age, and living arrangements: United States, 1968-69	55
35.	Population used in obtaining rates shown in this publication, by age and selected characteristics: United States, 1969	56
36.	Population under 65 used in obtaining rates shown in this publication, by age and se- lected characteristics: United States, 1968	57

Table 1. Average number of discharges from short-stay hospitals, rate per 1,000 persons, number of hospital days, average length of hospital stay for discharges, and number and percent of persons surgically treated, by age and sex: United States, 1968-69

# APPENDIX I

# TECHNICAL NOTES ON METHODS

### **Background of This Report**

This report is one of a series of statistical reports prepared by the National Center for Health Statistics (NCHS). It is based on information collected in a continuing nationwide sample of households in the Health Interview Survey (HIS).

The Health Interview Survey utilizes a questionnaire which obtains information on personal and demographic characteristics, impairments, illnesses, injuries, chronic conditions, and other health topics. As data relating to each of these various broad topics are tabulated and analyzed, separate reports are issued which cover one or more of the specific topics. The present report is based on data collected in household interviews during 1968 and 1969.

The population covered by the sample for the Health Interview Survey is the civilian, noninstitutional population of the United States living at the time of the interview. The sample does not include members of the Armed Forces or U.S. nationals living in foreign countries. It should also be noted that the estimates shown do not represent a complete measure of any given topic during the specified calendar period since data are not collected in the interview for persons who died during the reference period. For many types of statistics collected in the survey, the reference period covers the 2 weeks prior to the interview week. For such a short period, the contribution by decedents to a total inventory of conditions or services should be very small. However, the contribution by decedents during a long reference period (e.g. 1 year) might be sizable especially for older persons.

### Statistical Design of the Health Interview Survey

General plan. — The sampling plan of the survey follows a multistage probability design which permits a continuous sampling of the civilian, noninstitutional population of the United States. The sample is designed in such a way that the sample of households interviewed each week is representative of the target population and that weekly samples are additive over time. This feature of the design permits both continuous measurement of characteristics of samples, more detailed analysis of less common characteristics and smaller categories of health-related items. The continuous collection has administrative and operational advantages as well as technical assets since it permits fieldwork to be handled with an experienced, stable staff.

The overall sample was designed in such a fashion that tabulations can be provided for each of the four major geographic regions and for urban and rural sectors of the United States.

The first stage of the sample design consists of drawing a sample of 357 primary sampling units (PSU's) from approximately 1,900 geographically defined PSU's. A PSU consists of a county, a small group of contiguous counties, or a standard metropolitan statistical area. The PSU's collectively cover the 50 States and the District of Columbia.

With no loss in general understanding, the remaining stages can be combined and treated in this discussion as an ultimate stage. Within PSU's, then, ultimate stage units called segments are defined in such a manner that each segment contains an expected six households. (Prior to July 1, 1968, the expected segment size was nine households.) Three general types of segments are used:

> Area segments which are defined geographically.

> List segments, using 1960 Census registers as the frame.

Permit segments, using up-dated lists of building permits issued in sample PSU's since 1960.

Census address listings were used for all areas of the country where addresses were well defined and could be used to locate housing units. In general the list frame included the larger urban areas of the United States from which about two-thirds of the HIS sample was selected. The total HIS sample of approximately 8,000 segments yields a probability sample of about 134,000 persons in 42,000 interviewed households in a year.

Descriptive material on data collection, field procedures, and questionnaire development in the HIS has been published as well as a detailed description of the sample design and a report on the estimation procedure and the method used to calculate sampling errors of estimates derived from the survey.<sup>12-14</sup>

Collection of data. — Field operations for the survey are performed by the U.S. Bureau of the Census under specifications established by the National Center for Health Statistics. In accordance with these specifications the Bureau of the Census participates in survey planning, selects the sample, and conducts the field interviewing as an agent of NCHS. The data are coded, edited, and tabulated by NCHS.

*Estimation procedures*.—Since the design of the HIS is a complex multistage probability sample, it is necessary to use complex procedures in the derivation of estimates. Four basic operations are involved:

- 1. Inflation by the reciprocal of the probability of selection. The probability of selection is the product of the probabilities of selection from each step of selection in the design: PSU, segment, and household.
- Nonresponse adjustment. —The estimates are inflated by a multiplication factor which has as its numerator the number of sample households in a given segment and as its denominator the number of households interviewed in that segment.
- 3. First-stage ratio adjustment.—Sampling theory indicates that the use of auxiliary information which is highly correlated with the variables being estimated improves the reliability of the estimates. To reduce the variability between PSU's within a region, the estimates are ratio adjusted to 1960 population within six colorresidence classes.
- 4. Post-stratification by age-sex-color.—The estimates are ratio adjusted within each of 60 age-sex-color cells to an independent estimate of the population of each cell for the survey period. These independent estimates are prepared by the Bureau of the Census. Both the first-stage and post-stratified ratio adjustments take the form of multiplication factors applied to the weight of each elementary unit (person, household, condition, and hospitalization).

The effect of the ratio-estimating process is to make the sample more closely representative of the

civilian, noninstitutional population by age, sex, color, and residence, which thereby reduces sampling variance.

As noted, each week's sample represents the population living during that week and characteristics of the population. Consolidation of samples over a time period, e.g., a calendar quarter, produces estimates of average characteristics of the U.S. population for the calendar quarter. Similarly, population data for a year are averages of the four quarterly figures.

For prevalence statistics, such as number of persons with speech impairments or number of persons classified by time interval since last physician visit, figures are first calculated for each calendar quarter by averaging estimates for all weeks of interviewing in the quarter. Prevalence data for a year are then obtained by averaging the four quarterly figures.

For other types of statistics-namely those measuring the number of occurrences during a specified time period-such as incidence of acute conditions. number of disability days, or number of visits to a doctor or dentist, a similar computational procedure is used, but the statistics are interpreted differently. For these items, the questionnaire asks for the respondent's experience over the 2 calendar weeks prior to the week of interview. In such instances the estimated quarterly total for the statistic is 6.5 times the average 2-week estimate produced by the 13 successive samples taken during the period. The annual total is the sum of the four quarters. Thus the experience of persons interviewed during a year -experience which actually occurred for each person in a 2-calendarweek interval prior to week of interview-is treated as though it measured the total of such experience during the year. Such interpretation leads to no significant bias.

Explanation of hospital recall. - The survey questionnaire uses a 12-month recall period for hospitalizations. That is, the respondent is asked to report hospitalizations which occurred during the 12 months prior to the week of interview. Information is also obtained as to the date of entry into the hospital and duration of stay. Analysis of this information and also the results of special studies has shown that there is an increase in under-reporting of hospitalizations with increase in time interval between the discharge and the interview. Exclusive of the hospital experience of decedents, the net underreporting with a 12-month recall is in the neighborhood of 10 percent, but underreporting of discharges within 6 months of the week of interview is estimated to be less than 5 percent. For this reason hospital discharge data in this report are based on hospital discharges reported to have occurred within 6 months of the week of interview. Since the interviews were evenly distributed according to weekly probability

samples throughout any interviewing year, no seasonal bias was introduced by doubling the 6-month-recall data to produce an annual estimate for that year of interviewing. Doubling the 6-month data in effect imputes to the entire year preceding the interview the rate of hospital discharges actually observed during the 6 months prior to interview. However, estimates of the number of persons with hospital episodes (as opposed to estimates of the number of hospital discharges) are based on 12-month recall data since a person's 12-month experiences cannot be obtained by doubling his most recent 6-month experience.

### **General Qualifications**

*Nonresponse.*—Data were adjusted for nonresponse by a procedure which imputes to persons in a household which was not interviewed the characteristics of persons in households in the same segment which were interviewed. The total noninterview rate was about 5 percent--1 percent was refusal, and the remainder was primarily due to the failure to find an eligible respondent at home after repeated calls.

The interview process.—The statistics presented in this report are based on replies obtained in interviews of persons in the sampled households. For children and for adults not present in the home at the time of the interview, the information was obtained from a related household member such as a spouse or the mother of a child.

There are limitations to the accuracy of diagnostic and other information collected in household interviews. For diagnostic information, the household respondent can usually pass on to the interviewer only the information the physician has given to the family. For conditions not medically attended, diagnostic information is often no more than a description of symptoms. However, other facts, such as the number of disability days caused by the condition, can be obtained more accurately from household members than from any other source since only the persons concerned are in a position to report this information.

Rounding of numbers.—The original tabulations on which the data in this report are based show all estimates to the nearest whole unit. All consolidations were made from the original tabulations using the estimates to the nearest unit. In the final published tables, the figures are rounded to the nearest thousand, although these are not necessarily accurate to that detail. Devised statistics, such are rates and percent distribution, are computed after the estimates on which these are based have been rounded to the nearest thousand.

*Population figures*.—Some of the published tables include population figures for specified categories, Ex-

cept for certain overall totals by age, sex, and color, which are adjusted to independent estimates. these figures are based on the sample of households in the HIS. These are given primarily to provide denominators for rate computation, and for this purpose are more appropriate for use with the accompanying measures of health characteristics than other population data that may be available. With the exception of the overall totals by age, sex, and color mentioned above, the population figures differ from corresponding figures (which are derived from different sources) published in reports of the Bureau of the Census. (For population data for general use, see the official estimates presented in Bureau of the Census reports in the P-20, P-25, and P-60 series.)

### **Reliability of Estimates**

Since the statistics presented in this report are based on a sample, they will differ somewhat from the figures that would have been obtained if a complete census had been taken using the same schedules, instructions, and interviewing personnel and procedures.

As in any survey, the results are also subject to reporting and processing errors and errors due to nonresponse. To the extent possible, these types of errors were kept to a minimum by methods built into survey procedures. Although it is very difficult to measure the extent of bias in the Health Interview Survey, a number of studies have been conducted to study this problem. The results have been published in several reports.<sup>15-19</sup>

The standard error is primarily a measure of sampling variability, that is, the variations that might occur by chance because only a sample of the population is surveyed. As calculated for this report, the standard error also reflects part of the variation which arises in the measurement process. It does not include estimates of any biases which might lie in the data. The chances are about 68 out of 100 that an estimate from the sample would differ from a complete census by less than the standard error. The chances are about 95 out of 100 that the difference would be less than twice the standard error and about 99 out of 100 that it would be less than 2½ times as large.

The relative standard error of an estimate is obtained by dividing the standard error of the estimate by the estimate itself and is expressed as a percentage of the estimate. For this report, asterisks are shown for any cell with more than a 30-percent relative standard error. Included in this appendix are charts from which the relative standard errors can be determined for estimates shown in the report. In order to derive relative errors which would be applicable to a wide variety of health statistics and which could be prepared at a moderate cost, a number of approximations were required. As a result, the charts provide an estimate of the approximate relative standard error rather than the precise error for any specific aggregate or percentage.

Three classes of statistics for the health survey are identified for purposes of estimating variances.

Narrow range.—This class consists of (1) statistics which estimate a population attribute, e.g., the number of persons in a particular income group, and, (2) statistics for which the measure for a single individual during the reference period used in data collection is usually either 0 or 1 or on occasion may take on the value 2 or very rarely 3.

Medium range.—This class consists of other statistics for which the measure for a single individual during the reference period used in data collection will rarely lie outside the range 0 to 5.

Wide range.—This class consists of statistics for which the measure for a single individual during the reference period used in data collection can range from 0 to a number in excess of 5, e.g., the number of days of bed disability.

In addition to classifying variables according to whether they are narrow-, medium-, or wide-range, statistics in the survey are further defined as:

- Type A. Statistics on prevalence and incidence data for which the period of reference in the questionnaire is 12 months.
- *Type B.* Incidence-type statistics for which the period of reference in the questionnaire is 2 weeks.
- *Type C.* Statistics for which the reference period is 6 months.

Only the charts on sampling error applicable to data contained in this report are presented.

General rules for determining relative sampling errors....The "guide" on page 63, together with the following rules, will enable the reader to determine approximate relative standard errors from the charts for estimates presented in this report.

Rule 1. Estimates of aggregates: Approximate relative standard errors for estimates of aggregates such as the number of persons with a given characteristic are obtained from appropriate curves on pages 64-68. The number of persons in the total U.S. population or in an age-sex-color class of the total population is adjusted to official Bureau of the Census figures and is not subject to sampling error.

- Rule 2. Estimates of percentages in a percent distribution: Relative standard errors for percentages in a percent distribution of a total are obtained from appropriate curves on pages 65 and 68. For values which do not fall on one of the curves presented in the chart, visual interpolation will provide a satisfactory approximation.
- Rule 3. Estimates of rates where the numerator is a subclass of the denominator. This rule applies for prevalence rates or where a unit of the numerator occurs, with few exceptions, only once in the year for any one unit in the denominator. For example, in computing the rate of visual impairments per 1,000 population, the numerator consisting of persons with the impairment is a subclass of the denominator which includes all persons in the population. Such rates if converted to rates per 100 may be treated as though they were percentages and the relative standard errors obtained from the chart P4AN-M. Rates per 1,000 or on any other base, must first be converted to rates per 100; then the percentage chart will provide the relative standard error per 100.
- Rule 4. Estimates of rates where the numerator is not a subclass of the denominator: This rule applies where a unit of the numerator often occurs more than once for any one unit in the denominator. For example, in the computation of the number of persons injured per 100 currently employed persons per year, it is possible that a person in the denominator could have sustained more than one of the injuries included in the numerator. Approximate relative standard errors for rates of this kind may be computed as follows:
  - (a) Where the denominator is the total U.S. population or includes all persons in one or more of the agesex-color groups of the total population, the relative error of the rate is equivalent to the relative error of the numerator which can be obtained directly from the appropriate chart.
  - (b) In other cases, obtain the relative standard error of the numerator and of the denominator from the appropriate curve. Square each of these relative errors, add the re-

sulting values, and extract the square root of the sum. This procedure will result in an upper bound on the standard error and often will overstate the error.

Rule 5. Estimates of difference between two statistics (mean, rate, total, etc.): The standard error of a difference is approximately the square root of the sum of the squares of each standard error considered separately. A formula for the standard error of a difference  $d=X_1-X_2$  is

$$\sigma_{\rm d} = / (X_1 V_{\rm x1})^2 + (X_2 V_{\rm x2})^2$$

where  $X_1$  is the estimate for class 1,  $X_2$  is the estimate for class 2, and  $V_{x1}$ and  $V_{x2}$  are the relative errors of  $X_1$  and  $X_2$  respectively. This formula will represent the actual standard error quite accurately for the difference between separate and uncorrelated characteristics, although it is only a rough approximation in most other cases. The relative standard error of each estimate involved in such a difference can be determined by one of the four rules above, whichever is appropriate.

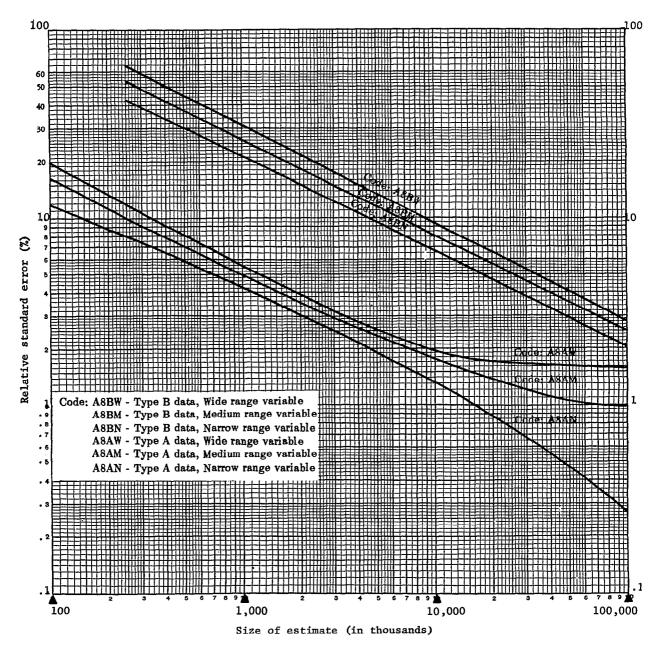

t,

# Guide to Use of Relative Standard Error Charts

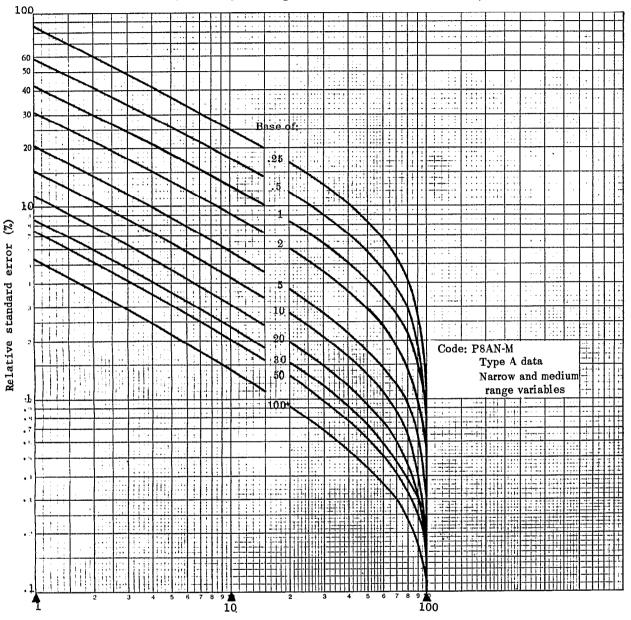

The code shown below identifies the appropriate curve to be used in estimating the relative standard error of the statistic described. The four components of each code described the statistics as follows: (1) A= aggregate, P= percentage; (2) the number of calendar quarters of data collection; (3) the type of the statistic; and (4) the range of the statistic as described on page 61.

	Use:					
Statistic	Rule	Code on	page			
Persons: Number of: Persons in the U.S. population or in any age-sex category thereof	Not subje	ect to sampling error				
Persons in any other population group	1	A8AN	64			
Persons by chronic limitation status	1	A8AN	64			
Percent distribution by limitation status	2	P8AN-M	65			
Percent distribution by hospital insurance coverage-	2	P4AN-M	68			
Discharges from short-stay hospitals: Number of discharges per year	1	A8CN	66			
Rate of discharges in U.S. population or in any age-sex category thereof	4(a)	A8CN	66			
Rate of discharges in any other population group	4(Ъ)	Numer.: A8CN Denom.: A8AN	66 64			
Number of hospital days per discharge	1	A8CW	66			
Hospital days per discharge (average length of stay)	4(b)	Numer.: A8CW Denom.: A8CN	65			
Physician and dentist visits: Visits in a year	1	A4BM	67			
Visits per person in U.S. population or in any age-sex category thereof	4(a)	A4BM	67			
Visits per person in any other population group per year	4(b)	Numer.: A4BM Denom.: A4AN	67 67			
Percent of persons with visit in past year	2	P4AN-M	68			
Disability days: Number of days per year	1	A8 BW	67			
Days per person in the U.S. population or any age- sex category thereof	4(a)	ASBW	67			
Days per person in any other population group (including work-loss among currently employed)	4(b)	Numer.: A8BW Denom.: A8AN	67 64			
Persons injured: Number of persons injured per year	1	A8BN	64			
Persons injured per 1,000 U.S. population or any age-sex category thereof	4(a)	A8 BN	64			
Persons injured per 1,000 population in any other population group	4(Ъ)	Numer.: A8BN Denom.: A8AN	64 64			

Example of use of chart: An aggregate of 5,000,000 (on scale at bottom of chart) for a Narrow range type A statistic (code: A8AN) has a relative standard error of 1.9 percent, read from scale at left side of chart, or a standard error of 95,000 (1.9 percent of 5,000,000). For a Wide range type B statistic (code: A8BW), an aggregate of 10,000,000 has a relative error of 9.3 percent or a standard error of 930,000 (9.3 percent of 10,000,000).

### Relative standard errors for percentages based on eight quarters of data collection for type A data, Narrow and Medium range

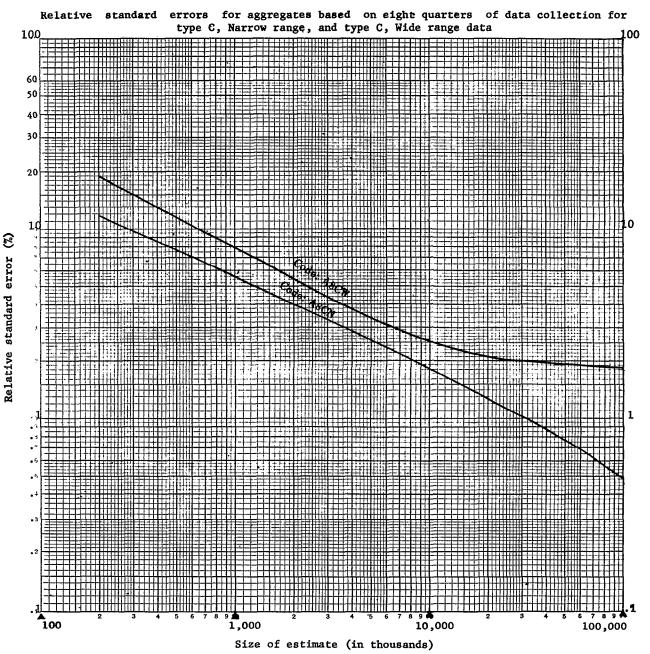

(Base of percentage shown on curves in millions)

Estimated percentage

I

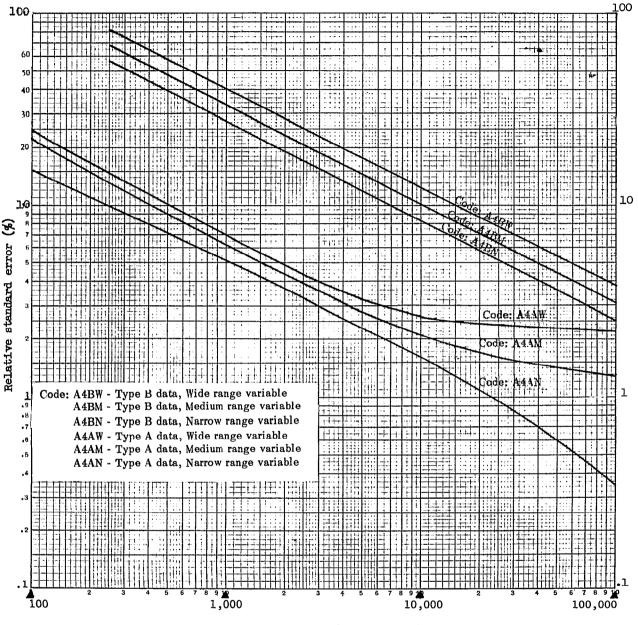

Example of use of chart: An estimate of 20 percent (on scale at bottom of chart) based on an estimate of 10,000,000 has a relative standard error of 2.8 percent (read from the scale at the left side of the chart), the point at which the curve for a base of 10,000,000 intersects the vertical line for 20 percent. The standard error in percentage points is equal to 20 percent X 2.8 percent or 0.56 percentage points.

65

Example of use of chart: An aggregate of 1,000,000 (on scale at bottom of chart) for a Narrow range type C statistic (code: A8CN) has a relative standard error of 5.6 percent, read from scale at left side of chart, or a standard error of 56,000 (5.6 percent of 1,000,000).

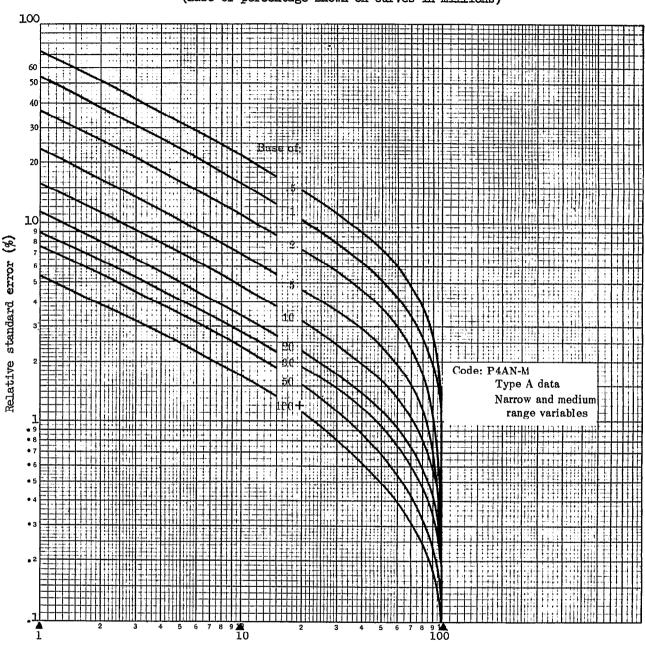

66

### Relative standard errors for aggregates based on four quarters of data collection for data of all types and ranges

Size of estimate (in thousands)

Example of use of chart: An aggregate of 2,000,000 (on scale at bottom of chart) for a Narrow range Type A statistic (code: A4AN) has a relative standard error of 3.6 percent, (read from scale at left side of chart), or a standard error of 72,000 (3.6 percent of 2,000,000). For a Wide range Type B statistic (code: A4BW), an aggregate of 6,000,000 has a relative error of 16.0 percent or a standard error of 960,000 (16 percent of 6,000,000).

Relative standard errors for percentages based on four quarters of data collection for type A data, Narrow and Medium range

(Base of percentage shown on curves in millions)

Estimated percentage

Example of use of chart: An estimate of 20 percent (on scale at bottom of chart) based on an estimate of 10,000,000 has a relative standard error of 3.2 percent (read from the scale at the left side of the chart), the point at which the curve for a base of 10,000,000 intersects the vertical line for 20 percent. The standard error in percentage points is equal to 20 percent X 3.2 percent or 0.64 percentage points.

# APPENDIX II

# DEFINITIONS OF CERTAIN TERMS USED IN THIS REPORT

#### Terms Relating to Hospitalization

Hospital discharge.—A hospital discharge is the completion of any continuous period of stay of 1 night or more in a hospital as an inpatient except the period of stay of a well newborn infant. A hospital discharge is recorded whenever a present member of the household is reported to have been discharged from a hospital in the 12-month period prior to the interview week. (Estimates were based on discharges which occurred during the 6-month period prior to the interview.)

Hospital.—For this survey a hospital is defined as any institution meeting one of the following criteria: (1) named in the listing of hospitals in the current Guide Issue of Hospitals, the Journal of the American Hospital Association; (2) named in the listing of hospitals in the Directories of the American Osteopathic Hospital Association; or (3) named in the annual inventory of non-Federal hospitals submitted by the States to the Health Care Facilities Service, Health Services and Mental Health Administration, in conjunction with the Hill-Burton program.

Short-stay hospital.—A short-stay hospital is one in which the type of service provided by the hospital is general; maternity; eye, ear, nose, and throat; children's; or osteopathic, or it may be the hospital department of an institution.

*Hospital day.*—A hospital day is a day on which a person is confined to a hospital. The day is counted as a hospital day only if the patient stays overnight. Thus a patient who enters the hospital on Monday afternoon and leaves Wednesday noon is considered to have had 2 hospital days.

Estimates of the total number of hospital days are derived by summing the days for all hospital discharges. (See definition of "Hospital discharge.")

Length of hospital stay.—The length of hospital stay is the duration in days, exclusive of the day of discharge, of a hospital discharge. (See definition of "Hospital discharge.")

Average length of stay.—The average length of stay per discharged patient is computed by dividing the total number of hospital days for a specified group by the total number of discharges for the same group.

#### Terms Relating to Physician Visits

*Physician visit*.—A physician visit is defined as consultation with a physician, in person or by telephone, for examination, diagnosis, treatment, or advice. The visit is considered to be a physician visit if the service is provided directly by the physician or by a nurse or other person acting under a physician's supervision. For the purpose of this definition, "physician" includes doctors of medicine and osteopathic physicians. The term "doctor" is used in the interview rather than "physician" because of the need to keep to popular usage. However, the concept toward which all instructions are directed is that which is described here.

Physician visits for services provided on a mass basis are not included in the tabulations. A service received on a mass basis is defined as any service involving only a single test (e.g., test for diabetes) or a single procedure (e.g., smallpox vaccination) when this single service was administered identically to all persons who were at the place for this purpose. Hence obtaining a chest X-ray in a tuberculosis chest X-ray trailer is not included as a physician visit. However, a special chest X-ray given in a physician's office or in an outpatient clinic is considered to be a physician visit.

If a physician is called to a house to see more than one person, the call is considered to be a separate physician visit for each person about whom the physician was consulted.

A physician visit is associated with the person about whom the advice was sought, even if that person did not actually see or consult the physician. For example, if a mother consults a physician about one of her children, the physician visit is ascribed to the child.

*Place of visit.*—The place of visit is a classification of the types of places at which a physician visit takes place. Definitions of the various categories are as follows:

1. Home is defined as any place in which the person was staying at the time of the physician's visit. It may be his own home, the home of a friend, a hotel, or any other place the person may be staying (except as an overnight patient in a hospital).

- 2. Office is defined as the office of a physician in private practice only. This may be an office in the physician's home, an individual office in an office building, or a suite of offices occupied by several physicians. For purposes of this survey, physicians connected with prepayment-group-practice plans are considered to be in private practice.
- 3. *Hospital clinic* is defined as an outpatient clinic or emergency room in any hospital.
- 4. Company or industry health unit refers to treatment received from a physician or under a physician's supervision at a place of business (e.g., factory, store, office building). This includes emergency or first-aid rooms located in such places if treatment was received there from a physician or trained nurse.
- 5. Telephone contact refers to advice given in a telephone call by the physician directly or through a nurse. (Calls for appointments are excluded.)
- 6. Other refers to advice or treatment received from a physician or under a physician's general supervision at a school, at an insurance office, at a health department clinic, or any other place at which a physician consultation might take place.

## Terms Relating to Dental Visits

Dental visit.- A dental visit is defined as any visit to a dentist's office for treatment or advice, including services by a technician or hygienist acting under a dentist's supervision.

## **Terms Relating to Conditions**

*Condition.*—A morbidity condition, or simply a condition, is any entry on the questionnaire which describes a departure from a state of physical or mental well-being. It results from a positive response to one of a series of "medical disability impact" or "illness-recall" questions. In the coding and tabulating process, conditions are selected or classified according to a number of different criteria such as whether they were medically attended, whether they resulted in disability, or whether they were acute or chronic; or according to the type of disease, injury, impairment, or symptom reported. For the purposes of each published report or set of tables, only those conditions recorded on the questionnaire which satisfy certain stated criteria are included.

Conditions except impairments are coded by type according to the Eighth Revision International Classification of Diseases, Adapted for Use in the United States (ICDA), with certain modifications adopted to make the code more suitable for a household interview survey. Chronic condition.—A condition is considered to be chronic if (1) the condition is described by the respondent as having been first noticed more than ( months before the week of the interview or (2) it is one of the conditions listed below which are considered to be chronic regardless of the date of onset:

Asthma	Tumor, cyst, or growth					
Hay fever	Stomach ulcer					
Tuberculosis	Kidney stones					
Repeated attacks of sinus trouble	Arthritis or rheumatism Mental illness					
Rheumatic fever	Diabetes					
Hardening of the arteries	Thyroid trouble or goiter					
High blood pressure	Any allergy					
Heart trouble	Epilepsy					
Stroke	Cancer					
Trouble with varicose veins	Hernia or rupture					
Hemorrhoids or piles	Prostate trouble					
Deafness or serious	Paralysis of any kind					
trouble with hearing	Repeated trouble with					
Serious trouble with see-	back or spine					
ing, even when wearing	Club foot					
glasses	Permanent stiffness or					
Cleft palate	deformity of the foot,					
Any speech defect	leg, fingers, arm, or					
Missing fingers, hand, or	back					
arm-toes, foot, or leg	Condition present since					
Palsy	birth					

Impairment.—Impairments are chronic or permanent defects, usually static in nature, resulting from disease, injury, or congenital malformation. They represent decrease or loss of ability to perform various functions, particularly those of the musculoskeletal system and the sense organs. All impairments are classified by means of a special supplementary code for impairments. Hence code numbers for impairments in the International Classification of Diseases are not used. In the Supplementary Code impairments are grouped according to the type of functional impairment and etiology. The impairment classification is shown in *Vital and Health Statistics*, Series 10, No. 48.<sup>20</sup>

## Terms Relating to Persons Injured

Injury condition.—An injury condition, or simply an injury, is a condition of the type that is classified according to the nature of injury code numbers (N800-N999) in the International Classification of Diseases. In addition to fractures, lacerations, contusions, burns, and so forth, which are commonly thought of as injuries, this group of codes includes effects of exposure, such as sunburn; adverse reactions to immunization and other medical procedures; and poisonings. Unless otherwise specified, the term injury is used to cover all of these. Since a person may sustain more than one injury in a single accident, e.g., a broken leg and laceration of the scalp, the number of injury conditions may exceed the number of persons injured.

Statistics of acute injury conditions include only those injuries which involved at least 1 full day of restricted activity or medical attendance.

Person injured.--A person injured is one who has sustained one or more injuries in an accident or in some type of nonaccidental violence (see definition of "Injury condition"). Each time a person is involved in an accident or in nonaccidental violence causing injury that results in at least 1 full day of restricted activity or medical attention he is included in the statistics as a separate "person injured;" hence one person may be included more than once.

The number of persons injured is not equivalent to the number of "accidents" for several reasons: (1) the term "accident" as commonly used may not involve injury at all; (2) more than one injured person may be involved in a single accident, so the number of accidents resulting in injury would be less than the number of persons injured in accidents; and (3) the term "accident" ordinarily implies an accidental origin, whereas "persons injured" as used in the Interview Survey includes persons whose injuries resulted from certain nonaccidental violence.

The number of persons injured in a specified time interval is always equal to or less than the incidence of injury conditions since one person may incur more than one injury in a single accident.

Class of accident. - Injuries, injured persons, and resulting days of disability may be grouped according to class of accident. This is a broad classification of the types of events which resulted in personal injuries. Most of these events are accidents in the usual sense of the word, but some are other kinds of mishap, such as overexposure to the sun or adverse reactions to medical procedures, and others are nonaccidental violence, such as attempted suicide. The classes of accidents are: (1) moving motor vehicle accidents, (2) accidents occurring while at work, (3) home accidents, and (4) other accidents. These categories are not mutually exclusive. For example, a person may be injured in a moving motor vehicle accident which occurred while the person was at home or at work. The accident class "motor vehicle" includes "home-motor vehicle" and "while at work-motor vehicle." Similarly, the classes "while at work" and "home" include duplicated counts, e,g,, "motor vehicle-while at work" is included under "while at work."

#### Terms Relating to Disability

Chronic activity limitation.—Persons are classified into four categories according to the extent to which their activities are limited at present as a result of chronic conditions. Since the usual activities of preschool children, school-age children, housewives, and workers and other persons differ, a different set of criteria is used for each group. There is a general similarity between them, however, as will be seen in the following descriptions of the four categories:

1.	Persons unable to carry on major activity for								
	their group (major activity refers to ability to								
	work, keep house, or go to school)								
	Preschool children: inability to take part in								
	ordinary play with other								
	children.								
	School-age children: inability to go to school.								
	Housewives: inability to do any house								
	work,								
	Workers and all								
	other persons: inability to work at a job or business.								

2. Persons limited in amount or kind of major activity performed (major activity refers to ability to work, keep house, or go to school) Preschool children: limited in amount or kind of play with other children, e.g., need special rest periods, cannot play strenuous games, or cannot play for long periods at a time. School-age children: limited to certain types of schools or in school attendance, e.g., need special schools or special teaching, cannot go to school full time or for long periods at a time. limited in amount or kind Housewives: of housework, i.e., cannot lift children, wash or iron, or do housework for long periods at a time.

Workers and all other persons: limited in amount or kind of work, e.g., need special working aids or special rest periods at work, cannot work full time or for long periods at a time, or cannot do strenuous work.

3. Persons limited but not in major activity (major activity refers to ability to work, keep house, or go to school)

Preschool children: not classified in this category.

School-age children: not limited in going to school but limited in participation in athletics or other extracurricular activities.

Housewives:	not limited in housework
	but limited in other ac-
	tivities such as church,
	clubs, hobbies, civic proj-
	ects, or shopping.
Workers and all	
other persons:	not limited in regular
	work activities but limit-

- work activities but limited in other activities such as church, clubs, hobbies, civic projects, sports, or games.
- 4. *Persons not limited in activities* Includes persons with chronic conditions whose activities are not limited in any of the ways described above.

*Disability.*—Disability is a general term used to describe any temporary or long-term reduction of a person's activity as a result of an acute or chronic condition.

Disability days.—Short-term disability days are classified according to whether they are days of restricted activity, bed days, hospital days, work-loss days, or school-loss days. All hospital days are, by definition, days of bed disability; all days of bed disability are, by definition, days of restricted activity. The converse form of these statements is, of course, not true. Days lost from work and days lost from school are special terms which apply to the working and school-age populations only, but these too are days of restricted activity. Hence "days of restricted activity" is the most inclusive term used to describe disability days.

*Restricted-activity day.*—A day of restricted activity is one on which a person substantially reduces the amount of activity normal for that day because of a specific illness or injury. The type of reduction varies with the age and occupation of the individual as well as with the day of the week or season of the year. Restricted activity covers the range from substantial reduction to complete inactivity for the entire day.

Bed-disability day,—A day of bed disability is one on which a person stays in bed for all or most of the day because of a specific illness or injury. All or most of the day is defined as more than half of the daylight hours. All hospital days for inpatients are considered to be days of bed disability even if the patient was not actually in bed at the hospital.

*Work-loss day.*—A day lost from work is a day on which a person did not work at his job or business for at least one half of his normal workday because of a specific illness or injury. The number of days lost from work is determined only for persons 17 years of age and over who reported that at any time during the 2-week period covered by the interview they either worked at or had a job or business. (See "Currently

employed persons" under "Demographic and Economic: Terms.")

## Terms Relating to Hospital Insurance

Health insurance.—Health insurance is any plar specifically designed to pay all or part of the medical or hospital expenses of the insured individual. The insurance can be either a group or an individual policy with the premiums paid by the individual, his employer. a third party, or a combination of these. Benefits received under the plan can be in the form of payment to the individual or to the hospital or doctor. However, the plan must be a formal one with defined membership and benefits rather than an informal one. For example, an employee simply paying the hospital bill for an employee would not constitute a health insurance plan.

For the Health Interview Survey, health insurance excludes the following kinds of plans: (1) plans limited to the "dread diseases" such as cancer and polio (2) free care such as public assistance, public welfare and medicaid, care given free of charge to veterans. care given under Uniformed Services Dependents Medical Care Program, care given under the Crippled Children Program or similar programs, and care of persons admitted to a hospital for research purposes; (3) insurance which pays bills only for accidents, such as liability insurance held by a car or property owner, insurance that covers children for accidents at school or camp, and insurance for a worker that covers him only for accidents, injuries, or diseases incurred on the job; and (4) insurance which pays only for loss of income.

Hospital coverage.—Insurance which pays all or part of the hospital bill for the hospitalized person is called hospital insurance. By hospital bill is meant only the bill submitted by the hospital itself, not the doctor's or surgeon's bill or the bill for special nurses. Such a bill always includes the cost of room and meals and may also include the costs of other services such as operating room, laboratory tests, and X-rays.

## Demographic and Economic Terms

Age.—The age recorded for each person is the age at last birthday. Age is recorded in single years and grouped in a variety of distributions depending on the purpose of the table.

*Color.*— The population is divided into two color groups, "white" and "all others." The "all other" group includes such people as Negro, American Indian, Chinese and Japanese, and any other race. Mexican persons are included with white unless definitely known to be Indian or of another race.

Income of family or of unrelated individuals.--Each member of a family is classified according to the total

income of the family of which he is a member. Within the household all persons related to each other by blood, marriage, or adoption constitute a family. Unrelated individuals are classified according to their own income.

The income recorded is the total of all income received by members of the family in the 12-month period preceding the week of interview. Income from all sources is included, e.g., wages, salaries, rents from property, pensions, and help from relatives.

*Marital status*.—Marital status is recorded only for persons 17 years of age or older. The marital status categories in this report are as follows:

Under 17 includes all persons aged 0-16 regardless of their marital status.

*Married* includes all married persons not separated from their spouses. Persons with commonlaw marriage are considered as married.

Never married includes persons who were never married and persons whose only marriage was annulled.

Separated includes married persons who have a legal separation or who have parted because of other reasons. This does not include persons separated from their spouses because of the circumstances of their employment or service in the Armed Forces; these persons are considered married.

*Widowed* and *divorced* include, respectively, all persons who said they were either widowed or legally divorced.

Living arrangement.—The four categories of living arrangements shown in this report are as follows:

*Living alone.*—Living alone is defined as persons living in one-member households.

*Living with nonrelatives.*—Living with nonrelatives is defined as persons living in a household with another person or persons, none of whom are related to him by blood, marriage, or adoption.

Living with relatives—married.—This category includes married persons who are living in a household with another person or persons, of whom one or more are related to him by blood, marriage, or adoption. Persons with commonlaw marriages are considered to be married. For purposes of this category "married" excludes widowed, divorced, or separated. Persons whose only marriage was annulled are counted as "never married."

Living with relatives—other.—This category includes persons who are widowed, divorced, separated, or never married who are living in a household with another person or persons, of whom one or more are related to him by blood, marriage, or adoption. Persons whose only marriage was annulled are counted as "never married." "Separated" refers to married persons who have a legal separation or who have parted because of marital discord.

*Geographic region*.—For the purpose of classifying the population by geographic area, the States are grouped into four regions. These regions, which correspond to those used by the U.S. Bureau of the Census, are as follows:

Region	States Included
Northeast	Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania
North Central	Michigan, Ohio, Indiana, Illinois, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, Kansas
South	Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Tennessee, Alabama, Mississippi, Arkansas, Louisiana, Oklahoma, Texas
West	Montana, Idaho, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, Alaska, Washington, Oregon, California, Hawaii

Area of residence.-- The place of residence of a member of the civilian, noninstitutional population is classified as inside a standard metropolitan statistical area (SMSA) or outside an SMSA and either farm or nonfarm.

Standard metropolitan statistical areas.—The definitions and titles of SMSA's are established by the U.S. Office of Management and Budget with the advice of the Federal Committee on Standard Metropolitan Statistical Areas. There were 212 SMSA's defined for the 1960 Decennial Census.

The definition of an individual SMSA involves two considerations: first, a city or cities of specified population which constitute the central city and identify the county in which it is located as the central county; and, second, economic and social relationships with contiguous counties (except in New England) which are metropolitan in character so that the periphery of the specific metropolitan area may be determined. SMSA's are not limited by State boundaries. Farm and nonfarm residence.—The population residing outside SMSA's is subdivided into the farm population, which comprises all non-SMSA residents living on farms, and the nonfarm population, which comprises the remaining outside-SMSA population. The farm population includes persons living on places of 10 acres or more from which sales of farm products amounted to \$50 or more during the previous 12 months or on places of less than 10 acres from which sales of farm products amounted to \$250 or more during the preceding 12 months. Other persons living outside an SMSA were classified as nonfarm if their household paid rent for the house but their rent did not include any land used for farming.

Sales of farm products refer to the gross receipts from the sale of field crops, vegetables, fruits, nuts, livestock and livestock products (milk, wool, etc.), poultry and poultry products, and nursery and forest products produced on the place and sold at any time during the preceding 12 months.

*Currently employed persons*.—Persons 17 years of age and over who reported that at any time during the 2-week period covered by the interview they either worked at or had a job or business are currently employed. Current employment includes paid work as an employee of someone else; self-employment in business, farming, or professional practice; and unpaid work in a family business or farm. Persons who were temporarily absent from a job or business because of a temporary illness, vacation, strike, or bad weather are considered as currently employed if they expected to work as soon as the particular event causing the absence no longer existed.

Free-lance workers are considered as currently employed if they had a definite arrangement with one employer or more to work for pay according to  $\varepsilon$ weekly or monthly schedule, either full time or part time.

Excluded from the currently employed population are persons who have no definite employment schedule but work only when their services are needed. Also excluded from the currently employed population are (1) persons receiving revenue from an enterprise but not participating in its operation, (2) persons doing housework or charity work for which they receive no pay, (3) seasonal workers during the portion of the year they were not working, and (4) persons who were not working, even though having a job or business, but were on layoff or looking for work.

The number of currently employed persons estimated from the Health Interview Survey (HIS) will differ from the estimates prepared from the Current Population Survey (CPS) of the U.S. Bureau of the Census for several reasons. In addition to sampling variability they include three primary conceptual differences, namely: (1) HIS estimates are for persons 17 years of age and over; CPS estimates are for persons 16 years of age and over. (2) HIS uses a 2-week reference period, while CPS uses a 1-week reference period. (3) HIS is a continuing survey with separate samples taken weekly; CPS is a monthly sample taken for the survey week which includes the 12th of the month.

<sup>1</sup>Conditions except impairments are coded according to the International Classification of Eiseases Adapted with certain modifications; impairments are coded according to a special supplementary classification referred to as the "X-Code." Numbers preceded by the letter "X" refer to this special supplementary classification. The impairment classification is shown in Vital and Health Statistics, Series 10, No. 48. If the conditions included in an ICCA number are equivalent to those included in an X-Code category, the ICCA number is not used.

<sup>2</sup>With .9 in the 4th digit.

<sup>3</sup>Other than .9 in the 4th digit.

# APPENDIX III. QUESTIONNAIRE

The items below show the exact content and wording of the basic questionnaire used in the nationwide survey of the U.S. National Health Survey. The actual questionnaire is designed for a household unit and includes additional spaces for reports on more than one person, condition, accident, or hospitalization. Such repetitive spaces are omitted in this illustration.

### Flash Cards Used With HIS-I(1969) -- Continued

## VITAL AND HEALTH STATISTICS PUBLICATION SERIES

#### Formerly Public Health Service Publication No. 1000

- Series 1. Programs and collection procedures.—Reports which describe the general programs of the National Center for Health Statistics and its offices and divisions, data collection methods used, definitions, and other material necessary for understanding the data.
- Series 2. Data evaluation and methods research.—Studies of new statistical methodology including: experimental tests of new survey methods, studies of vital statistics collection methods, new analytical techniques, objective evaluations of reliability of collected data, contributions to statistical theory.
- Series 3. Analytical studies.—Reports presenting analytical or interpretive studies based on vital and health statistics, carrying the analysis further than the expository types of reports in the other series.
- Series 4. Documents and committee reports.—Final reports of major committees concerned with vital and health statistics, and documents such as recommended model vital registration laws and revised birth and death certificates.
- Series 10. Data from the Health Interview Survey.—Statistics on illness, accidental injuries, disability, use of hospital, medical, dental, and other services, and other health-related topics, based on data collected in a continuing national household interview survey.
- Series 11. Data from the Health Examination Survey.—Data from direct examination, testing, and measurement of national samples of the civilian, noninstitutional population provide the basis for two types of reports: (1) estimates of the medically defined prevalence of specific diseases in the United States and the distributions of the population with respect to physical, physiological, and psychological characteristics; and (2) analysis of relationships among the various measurements without reference to an explicit finite universe of persons.
- Series 12. Data from the Institutional Population Surveys Statistics relating to the health characteristics of persons in institutions, and their medical, nursing, and personal care received, based on national samples of establishments providing these services and samples of the residents or patients.
- Series 13. Data from the Hospital Discharge Survey.—Statistics relating to discharged patients in short-stay hospitals, based on a sample of patient records in a national sample of hospitals.
- Series 14. Data on health resources: manpower and facilities.—Statistics on the numbers, geographic distribution, and characteristics of health resources including physicians, dentists, nurses, other health occupations, hospitals, nursing homes, and outpatient facilities.
- Series 20. Data on mortality.—Various statistics on mortality other than as included in regular annual or monthly reports—special analyses by cause of death, age, and other demographic variables, also geographic and time series analyses.
